The black vice industry and the Chinese vice industry were internally different. The black vice industry consisted of streetwalkers and pimps who settled quarrels with fights. The Chinese vice industry consisted of syndicated brothels which resolved severe business rivalries by gang wars, but adjudicated individual quarrels. The American public's appetite for illegal services does not explain these black-Chinese differences, although it does explain why both ethnic minorities entered the metropolitan vice industry at all. Demographic and cultural characteristics of blacks and of Chinese are needed to explain black-Chinese differences in internal organization of the vice industry.

As normalization of the American sex ratio set in (roughly, after 1914), the public's demand for vice services slackened, and ethnic-staffed vice industries found trade declining. Vice businesses then sought new employments to shore up the declining wages of sin. For the Chinese, the decline of white-patronized vice encouraged the restaurant/tourist industry in Chinatowns. This shift was largely complete by 1940. It represents a case of industrial succession in which an illegal industry disappeared and a legal one replaced it. Among blacks, the decline of white-patronized vice resorts stimulated a parallel search for alternative revenues. In the period between 1920-1944, this redeployment began to take the form of a rudimentary nightclub industry, but race riots and juvenile street crime aborted the

industrial succession after 1944. For both the Chinese and the blacks, therefore, a search for new opportunities arose in response to the declining profits of the white-oriented vice industry. But in the black case, industrial succession fizzled whereas in the Chinese case it succeeded. Cultural and demographic characteristics of the two minorities account for the black-Chinese difference in succession, but the general shift of public demand does not.

The Vice Industry, 1880-1924

Prior to the First World War, brisk public demand for prostitutes, gambling halls and drugs encouraged Chinese and blacks to enter the vice industry. In fact, American Chinatowns and urban black communities in this country were municipal vice centers throughout most of this period (Light, 1974; Frazier, 1949:645; Myrdal, 1944:332; Chicago Vice Commission, 1911:37-8; Hepler, 1972:71; Staples, 1973:81; Katzman, 1973:17; Reckless, 1925:173). Ethnic response to American demand supports the prevailing anomie theory of illegal enterprise because American society was encouraging blacks and Chinese to enter the illegal industry with financial rewards for their participation while their efforts to earn money in legal industries were rewarded much more modestly or not at all.

A massive preponderance of Chinese men existed before Chinatowns turned into municipal vice colonies (Light, 1974). Of course, this preponderance was encouraged and prolonged by the Immigration Act of 1882 and subsequent restrictive legislation. However, the drastic shortage of women in the Chinese population antedated the first restrictive legislation by three decades, thus proving that sex-ratio imbalances among Chinese were not the exclusive result of restrictive U.S. legislation (see Lyman, 1970:18). In 1890 there were 2,678.9 Chinese men for every 100 Chinese women in the United States (Table 2). Although this imbalance was much more extreme than in the case of the foreign-born whites, its origin was also a sojourning attitude among immigrant Chinese men who left their families at home.

In general, a slight surplus of nubile women prevailed among urban blacks (Table 3). This surplus of females among urban blacks was a permanent feature of urban black populations and did not tend toward normalization. On the other hand, large cities had quite different demographic profiles, so the overall surplus of women among black urbanites concealed important city-by-city variation. New York City was an outstanding example of the general surplus of women among urban black populations (Scheiner, 1965:115; DuBois, 1903:2-3), but Chicago began the twentieth century with a surplus of black males and, over three decades, developed a surplus of women. The city-by-city complexity (Table 4) of black demography increases the difficulty of framing reliable generalizations. Coupled with unresolved historical ambiguities, this problem rendered it necessary to restrict archival research to New York City where a stronger than average surplus of black women admittedly existed. However, references to other cities are presented anyway because a surplus of black women was the master trend. Surplus-of-males cities (Detroit, Chicago) are exceptions which one might examine for confirmation of the effect of demography upon the organization of prostitution. In all cases, however, effective public demand for prostitutes was regional, rather than municipal in scope because transients were preponderant consumers of vice services (Chicago Vice Commission, 1911:114-6, 228). Relative to foreign-white or Chinese populations of their regions, even the most pronouncedly male, urban black populations (Table 4) were

generously endowed with needy females.

The contrasting sex ratios of Chinese (surplus of men) and urban blacks (surplus of women) had divergent effects upon the white-patronized, ethnic-staffed vice industries both developed. The shortage of women in Chinatowns encouraged brothel prostitution and eliminated streetwalking. All Chinese prostitutes were full-time professionals and worked in brothels. On the other hand, the abundance of women in most black enclaves encouraged streetwalkers rather than professionally-staffed brothels. Quite unlike Chinatowns, urban black enclaves conducted prostitution in three distinct and mutually competitive modes. The least organized but largest class of black prostitutes was independent streetwalkers. In nearly all cases, these were unemployed women who turned to prostitution until marriage or a regular job

provided alternative support. Their number waxed and waned with the business cycle (Waterman, 1932:118). The next rung up the ladder of organization was the pimp system. Gun-toting black pimps maintained "strings" of 1-15 black and nonblack prostitutes who solicited business on streets and in saloons (Haller, 1970:220-1). In a few cases, pimps claimed a regular territory within which they exercised a monopoly, excluding all competition by threat of violence. However, most pimps were content to let prostitutes fend for themselves, insisting only upon a share of the gain in return for social-emotional support and a modicum of physical-legal protection (Slim, 1967; 1969). Black enclaves also contained syndicated brothels in which 3-100 prostitutes worked and resided. A brothel syndicate consisted of 2-15 brothels, each of which operated under a "franchise" from a common management (Reckless, 1933:70-1). As in Chinatowns, the franchising management provided personnel, corruption, and protection for resorts in its syndicate. Some syndicated brothels were expensive and elegant; others were cheap and dilapidated (Drake and Cayton, 1962:I, 55). In general, however, brothel prostitutes charged higher prices than streetwalking prostitutes and these, in turn, charged higher prices than the unemployed women of the ghetto.

In nearly all cases, syndicated brothels in black enclaves were under the management of white businessmen, although prostitutes were both black and nonblack (Landesco, 1968:27; Katzman, 1973:191).¹ Deliberate racial policy and high prices restricted these brothels to white customers. On the other hand, black men were the only pimps in black neighborhoods. Pimps had both black and nonblack prostitutes (Haller, 1972:221), and many grew wealthy in the business, but they rarely moved beyond pimping to brothel operation or from brothels to syndication. The

three levels of organization (brothels, pimps, streetwalkers) competed with one another for customers. Since white syndicates had political influence, they recurrently employed police to drive away price-cutting streetwalkers, but evicted blacks doggedly returned (Landesco, 1968:34, 42n; Reckless, 1933:69-70). The see-saw battle between streetwalking blacks and white-controlled brothels cast the pimps in the role of champions of their underdog race in competition with faceless white vice-lords (cf. Staples, 1973:92).

Black pimps relied upon their reputation for violent prowess to intimidate workers and rival pimps. Maintaining one's reputation required frequent dueling, and beatings or murders of prostitutes (Light, 1976). However, this ubiquitous violence never triggered wars between rival gangs in local, much less national federations. There is no record of inter-syndicate warfare for control of vice in black enclaves, although brothel syndicates made repeated, but ultimately futile efforts to eliminate price-cutting competitors. Here the situation in black vice districts forms a sharp contrast with the situation in Chinatowns. The black enclaves had high homicide rates, but no gang wars. Streetwalkers and their confederates frequently robbed their customers and, occasionally, robberies eventuated in killings (Asbury, 1940:127-8; Light, 1976). Chinatowns had low homicide rates, rampant gang wars, but no record of street robberies of visiting men. The implication is that the syndication of vice in Chinatowns prevented petty robberies and unregulated conflicts among individuals, but encouraged collective struggles for business advantage. On the other hand, the free market organization of vice in black enclaves permitted individualistic killings and petty crime, but eliminated gang warfare.

Although the surplus of women in the urban black population encouraged streetwalking rather than brothels, the presence of white-owned brothel syndicates in black enclaves prior to World War I proves that the abundance of needy black women did not altogether preclude brothel syndication. However, the strik-

¹ An exception was Mrs. Vina Fields, "a colored woman who has one of the largest houses in the city. During the [Chicago World's] Fair she had over 60 girls in her house, all colored, but all for white men" (Stead, 1894:247). Robert H. Spriggs, a Negro, also operated "several disreputable resorts" in New York's black ghetto in 1906 (Light, 1976).

ing shortage of black-owned brothel syndicates suggests that contrasting cultural heritages contributed to black-Chinese differences in organization of the ethnic vice industry. In the Chinese case, the vice industry consisted entirely of resorts owned by or affiliated with a Chinese secret society. These societies (*tongs*) traced their parentage in ritual to the Triad Society of South China and its Chee Kung Tong affiliate in San Francisco (Light, 1974). These historic origins have occasioned confusion because all Chinese tongs in this country trace an "affiliation" to the Triad Society through the Chee Kung Tong. However, most tongs were business, fraternal or political in character, and only a minority of "fighting tongs" licensed illegal businesses. Since complex alliances knit the nation's fighting tongs together, a purely local dispute could and often did precipitate a fight between affiliates and their allies in every U.S. Chinatown.

Lacking the Triad Society or any functional equivalent, black migrants of the lower class did not arrive with a culturally-provided framework around which to organize a syndicated vice industry. On the contrary, conditions of black life in the South (Jim Crow, free enterprise, police laxity) had encouraged the emergence of the lower-class cultural ideal of the "bad nigger," epitomized by the Stackolee legend (Johnson, 1941:99, 102), 103; Botkin, 1944:122-30). This legendary bully derived his fearsome reputation from violent prowess rather than from organizational affiliations. In the municipal vice industry, this cultural tradition evidently encouraged a free market organization around an internally competitive cadre of pimps. Additionally, the father-absent pattern in the black lower class placed primary earnings responsibilities upon black women heads of households with meager chances in industrial labor (Scheiner, 1965:57-8). Reinforcing the demographic abundance of these women, burdensome earning responsibilities naturally encouraged prostitution as supplementary or interim income. The resulting large class of part-time prostitutes constituted the major organizational barrier to professional monopoly in black-

controlled prostitution. If the Stackolee tradition offered scant support for monopolization, the ubiquity of inexpensive prostitutes additionally impeded it.

The intriguing problem of the demographic versus cultural origins of black-Chinese differences in the organization of the ethnic vice industry is inconsequential for the restricted purposes of this paper. Whether demographic or cultural in origin, or some combination of the two, the black-Chinese contrast in organization of the vice industry always reflected ethnic differences. Admittedly, American society encouraged both groups to sell vice services, but the demand of American buyers does not account for the contrasting organization of the supply. Therefore, a structural explanation of black and Chinese participation in the vice industry cannot fully account for the phenomena and requires supplementation by close review of contributory characteristics, demographic and socio-cultural, of sub-groups.

Industrial Succession, 1915-1940

The erosion of public demand for vice occasioned a search for alternative earning opportunities in Chinatowns as well as in urban black enclaves. However, cultural and demographic differences in black and Chinese populations also affected the outcome of this redirection, which was not simply a mechanical readjustment to market forces. For the Chinese, a restaurant-based tourist industry slowly supplanted the older vice industry (Light, 1974). Like its predecessor, the tourist industry depended upon patronage by non-Chinese. However, the tourist industry catered to women as well as to men, and even permitted the accommodation of children. In these respects, the developing tourist industry reflected the normalization of the sex ratio in American society, the growth of husband-wife families, and the increase in children. Although the transition from vice to tourism provided the occasion for a flurry of conflict at the turn of the century between opposing industrial interests within the Chinese communities, the basis for the conflict evaporated when fighting tongs

discovered the profitability of tourist enterprises. Fighting tongs actually opened restaurants on premises previously occupied by brothels and gambling halls.

In Northern black communities, the interwar years (1919-1939) also saw the development of an incipient tourist-entertainment industry catering to white outsiders (Reckless, 1925:278; Chicago Commission on Race Relations, 1922:202, 323-5; Light, 1976). These began as speakeasies in the Prohibition period and, like the brothels of the pre-Prohibition decades, were usually owned by white racketeers affiliated with outside crime syndicates (Waterman, 1932:128-9; McKay, 1940:200-1; Landesco, 1968:33). Speakeasies attracted white couples rather than single men; their entertainment consisted of suggestive revues and jazz music (Hobson, 1939: 214) rather than gambling or prostitution. Numerous restaurants purveying "soul" cuisine also opened to accommodate the gustatory curiosity of whites. These restaurants attracted favorable attention in the general news media (Light, 1976; James, 1931:248; Osofsky, 1963:32-3). Naturally, the interwar development of black communities as legitimate but risqué musical, entertainment, and restaurant attractions for affluent whites did not supplant the black neighborhoods' older attraction—prostitution (Waterman, 1932:128; Myrdal, 1944:977-8). This illicit business continued to attract white customers although the syndicated brothels disappeared, their white proprietors often shifting capital into cabarets and speakeasies. What is crucial in this interwar period, however, is the incipient separation of entertainment and vice, each industry attracting a different clientele (Guilds' Committee, 1939:257-63). The vice industry attracted unmarried men alone or in groups (Committee of Fourteen, 1928:22). They came to patronize vice resorts. The tourist industry attracted both men and women as couples, married as well as unmarried, and those who came were typically of middle or upper social status (Strong, 1940:100-1; Committee of Fourteen, 1930:21; Committee of Fourteen, 1927). The purpose of the tourists was to thrill to the depravity of nearby vice resorts, to

experience a "Negro" atmosphere, and to patronize jazz cabarets and "soul" restaurants (Osofsky, 1963:151; Reckless, 1925:88, 278). However contrived and superficial, the emergent tourist industry in Harlem, Chicago's South Side and most other metropolitan black enclaves authentically reflected a new public appreciation of black cultural forms, especially jazz music (Huggins, 1971:118). Indeed, jazz music was originally called "whorehouse" music in recognition of the setting in which its originators performed. The acceptance of jazz by respectable whites was a reflection of the underlying change in economic function of the black neighborhoods in the intervening half-century (Leonard, 1962:36, 50-1).

Yet, despite this substantial beginning, white tourism collapsed after 1944 and never recovered. Why did this industry collapse? One contributor was the Great Depression. The Depression had a deflationary impact upon the nightclub industry in general, and the repeal of Prohibition in 1933 was a specific shock for black belt speakeasies which could no longer rely upon police corruption to protect them from outside competition (Guilds' Committee, 1939:262). However, black belt clubs were among the most resilient of any in the nightclub industry, many reports indicating that they continued to operate "at full blast" throughout the Depression (Light, 1975; 1976).

Street robberies by juvenile criminals ("muggers")—not the Great Depression—finally killed the incipient tourist-entertainment industry in Harlem and other black neighborhoods. Of course, these robberies had always occurred in metropolitan vice districts (Scheiner, 1965:120; DuBois, 1899:238, 249, 252; Reckless, 1925:71). Riis (1892:221), Thrasher (1933:138) and Shaw (1930) all reported that "jackrolling" drunks and bawdy-house patrons was a typical apprenticeship in crime for adult offenders, and black men and boys were pronouncedly active in this form of robbery—an association which is hardly surprising in view of their residential proximity to centers of prostitution. Naturally, robberies and beatings reduced the volume of trade in a red-light district. In-

deed, a major recommendation of the more expensive, syndicated brothels was the customers' assurance of personal safety in them.

However, a tourist district required higher standards of street safety than a red-light district (Walker, 1933:252), and the proprietors of cabarets, dance palaces and other tourist attractions did, in fact, make strenuous efforts to protect tourists against thugs (Light, 1976). However, these efforts proved insufficient because of a sharp increase in the volume of juvenile delinquency in black neighborhoods beginning in the mid-1930s. The contemporary black and white press was acutely aware of this increase (Light, 1975, 1976) attributing it to Depression-spawned unemployment, and the constantly growing number and proportion of young blacks among the urban population (Table 5). Also, during the Second World War, when military personnel on liberty attempted to find "girls" in urban black neighborhoods, they came into conflict with local youths. The ensuing fights and race riots aggravated an already delicate situation, and wartime black neighborhoods acquired a reputation for danger which kept tourists at home (Lait and Mortimer, 1950:44, 46-7).

The mugging problem in black neighborhoods requires additional explanation because Chinatowns did not have this problem. It is a temptation to credit the Confucian family for suppressing juvenile delinquency, thus encouraging the tourist

industry in Chinatowns (President's Commission, 1967:74). However, this popular view assigns credit to the Chinese family when, as Lyman (1974:113) has observed, a safer explanation lies with the absence of families (no women) and, thus, of juveniles in Chinatown. In addition, Light and Wong (1975) have called attention to the growth in juvenile delinquency in American Chinatowns since the resumption of mass immigration following the Naturalization and Immigration Act of 1965. This abrupt increase raises additional doubt about the allegedly delinquency-resistant Confucian family.

Unlike Chinatowns, of course, urban black enclaves had always had an abundance of women of childbearing age. Largely because of rapid natural increase, the proportion of black juveniles to the urban juvenile population continuously increased, variously exceeding the general proportion of blacks between 1930 and 1950 (Table 5). This demographic process alone was enough to increase the incidence of juvenile crime in black neighborhoods. In contrast, the protracted shortage of women in the Chinese population retarded natural increase in population and, therewith, the delinquency problem in Chinatowns. Insofar as the father-absent cultural pattern in lower-class black families exacerbated delinquency and the Confucian family minimized it, black-Chinese cultural differences accentuated discrepancies in rates of delinquency which black-Chinese demo-

graphic contrasts engendered (McCord, 1968:91; Short, 1968:77). Withal, pronounced black-Chinese differences in rates of delinquency had a severe impact upon the developing tourist industry, for a tourist industry could not exist where delinquency was uncontrollable. Therefore, industrial succession (vice-tourism) took place in one case, but not in the other; and cultural and demographic characteristics of subgroups are required to explain the divergence.

CONCLUSION: DEMAND DOES NOT EXPLAIN SUPPLY

This historical comparison of blacks and Chinese confirms the claim that American society channelled disadvantaged minorities into illegal industries. But a close review also shows that no purely demand theory can account entirely for style, organization or succession in illegal enterprise because socio-cultural and demographic characteristics of minorities also affected these outcomes. Indeed, a shift in public demand (less vice, more tourism) had sharply contrasting consequences in Harlem and in Chinatowns because of contrasting demographic and sociocultural characteristics of inhabitants. So powerful were these demographic and sociocultural characteristics that a lucrative demand (tourism) had to abandon Harlem as well as other metropolitan black enclaves.

These anomalies point up a weakness of prevailing sociological analysis of illegal enterprise: the assumption that, given a demand schedule, disadvantage in the labor market is the only or, at least, the only substantial determinant of supply. In fact, even given a public demand and a high level of disadvantage, the quantity and quality of the supply of vice engendered still depended upon demographic, cultural and social organizational characteristics of blacks and Chinese. Indeed, some economic demands (tourism) produced no supply because of street crime engendered by adverse demographic and socio-cultural characteristics among potential suppliers.

Neither the old-fashioned import theory

nor the anomie theory alone can explain these results. This finding strengthens the hypothesis that illegal enterprise represents a fusion between what the American public wanted to buy (demand) and what, and how much disadvantaged subgroups (supply) have been willing or able to sell. True, providers can only sell what customers will buy. But, given a consumer demand for illegal products or services, the manner in which providers respond depends upon socio-cultural and demographic characteristics closely linked to ethnicity. Demand does not, therefore, explain supply because provider culture, social organization and demography intervene.

Although this conceptual adjustment is simple, its implications are uncharted. For example, sociologists acknowledge the importance of entrepreneurship in business so why not criminal entrepreneurship? The concept of criminal entrepreneurship enormously complicates the analysis of illegal enterprise because it implies that endowed groups can exploit niggling opportunities whereas others may flub Heaven-sent opportunities for illegal gain. Breaking the one-to-one correspondence of structural disadvantage and illegal enterprise, the concept of criminal entrepreneurship compels an analyst to inquire how groups are exploiting the illegal opportunities around them. Successful exploitation of illegal opportunities raises the cost of redirecting providers into legal occupations because only highly remunerated occupations can match or equal the livelihood illegal enterprise offers.

But what constitutes criminal entrepreneurship? Ordinary business skills contribute, but presumably do not exhaust the role. For example, Quakers are well endowed for business and have prospered in trade, but their religion precludes violence. Hence Quakers are unendowed for illegal enterprise even though highly endowed for business. In most cases, also, syndication in illegal enterprise requires the exclusion of small fry in the interest of maximum profit for the excluding in-group. Thus, when entrepreneurship is naively identified with scale of operation, the most entrepreneurial groups become

those who restrict participation the most—an obvious irony.

These ruminations merely illustrate the problems which the new direction implies. Admittedly, this horizon is stormy, but what is the alternative? Clinging to the time-honored theory of structural disadvantage is impossible because empirical objections are too easy to substantiate. A more mature view begins with the insistence that American society thrusts opportunities for lucrative deviance upon the disadvantaged, but acknowledges that socio-cultural and demographic characteristics determine the manner in which providers respond. The sociology of the problem then revolves around framing empirically-grounded generalizations to fit the diverse articulations between illegal industries and provider subgroups.

THE EXPANSION OF NATIONAL EDUCATIONAL SYSTEMS: TESTS OF A POPULATION ECOLOGY MODEL *

FRANÇOIS NIELSEN
McGill University

MICHAEL T. HANNAN
Stanford University

American Sociological Review 1977, Vol. 42 (June):479-490

This paper investigates the expansion of enrollments in national systems of education during the 1950-1970 period, from the point of view of the population ecology of organizations. A simplified dynamic model of the growth of a population of educational organizations is estimated using various techniques for pooling time series of cross-sectional data. Results lend support to a meta-model of growth in which the dynamic parameters of the process are the dependent variables. Structural inertia, the effects of resources and available candidates are found to depend in a systematic way on structural properties of the educational organizations (cost intensity and the complexity of the division of labor) and characteristics of the national environment (abundance of resources). The findings indicate the usefulness of the ecological approach for the analysis of organizational change.

Most research on organization-environment relations concerns itself with the effects of environmental variations on well-established organizations. However, Stinchcombe (1965) has argued persuasively that environmental impacts are strongest at the time of founding. If so, the impacts of environments on organizations will be seen most clearly on new or emergent organizations. Following Stinchcombe, we propose to study environmental impacts by examining the societal conditions for organizing. The creation and expansion of formal organization

demands both the existence of certain social organizational features (e.g., market economy, bureaucratic state administration, etc.) and the mobilization of personnel and other resources. Resources can be mobilized only at the expense of other existing or potential forms of organization. That is, if certain material and human resources are to be devoted to a certain form of organized activity, they are not available to other forms of activity. Consequently, forms of organization compete for resources. Insofar as forms of organizations both compete for resources and differ in their demands on the environment, the theoretical strategy of population ecology can be employed to model the differential expansion of the various forms of organization (Hannan and Freeman, 1974; 1977).

We focus on the expansion of one par-

ticular class of organization: educational organizations. Formal schooling has expanded enormously in every nation in the world over the past twenty-five years (Meyer et al., 1976). However, the rate of expansion varies greatly from nation to nation. We propose to use these variations to test an elementary population ecology model.

The expansion of education is most commonly explained by reference to the demands of modern industrial and bureaucratic production systems. Education viewed from the perspective of the individual consumer is an asset in competition for scarce rewards. Viewed from the perspective of the labor market or the firm, education is either a productive asset or a signal of some learning or productive ability (Machlup, 1970). Expansion of those forms of activity that demand skills in processing information will tend to increase the demand for education. Even if schooling does not affect productivity, its use as a signal for productive skills will tend to activate a competition for education that will lead to increasing levels of investment by individuals in education (Collins, 1971; Boudon, 1974). In either case, education is treated as a property of individuals that affects their relationship to the production system.

The expansion of education also has strategic value to political elites committed to changing the relationship of the individual to the state or polity. There is a good deal of evidence that education is used to define or redefine status categories in the population and thereby regulate or alter the position of those obtaining education in the polity (Rubinson, 1973; Ramirez, 1973; Meyer, 1971). Insofar as there are advantages to state controllers in mobilizing the populations politically and as long as expanding educational systems is a convenient or effective way to this end, education will be expanded. Although this argument is quite different from productivity and signaling arguments, it too treats education as a property of individuals that affects their relationship to the larger system.

We do not dispute either explanation. The trend toward greatly increased schooling undoubtedly reflects increased demands for knowledge, increased reliance on formal certification, status and class competition for jobs and other scarce rewards, and changes in the relationship of the state to its members. Yet we are unwilling to presume that any social system obtains any outcome it needs—in this case, increased schooling—simply by virtue of needing it. Nor do individuals automatically find schools or places in schools by virtue of desiring schooling. Schooling is an organized activity and the expansion of schooling represents an organizational achievement. Schooling expands in a system only when there is demand (from either the controllers of the system or the members) for additional schooling *and* an organizational capacity to incorporate more students. Previous research has emphasized the former at the expense of the latter. We propose that the expansion of formal educational organizations in any society be analyzed in specifically organizational terms.

Educational organizations differ on at least two variables of organizational significance. The first, *complexity*, particularly complexity of the division of labor, increases regularly from primary schools to universities. The second dimension is *unit-cost*, the amount of resources needed to process one student. Differences in costs for staff and equipment and the increasing burden of the indirect cost entailed by the nonproductivity of a more valuable fraction of the potential labor force means that unit-cost also increases from primary schools to universities.

Thus, we can define three *forms* of educational organizations: primary, secondary and tertiary, distinguished by their relative positions on the scales of complexity and unit-cost. If the environments of educational organizations are delimited by national boundaries, the collection of schools at a given level within a particular country constitutes a *population* of organizations. Finally, the three populations of organizations (primary, secondary and

tertiary schools), interacting within the same national environment, constitute a *community* of organizations.

Organizational forms, populations and communities of organizations constitute three basic ingredients of a population-ecological analysis of organizations, as explicated by Hannan and Freeman (1974; 1977). In this paper, we focus on the *aggregate size* of populations of organizations, measured as the national enrollment in a given educational level.

1. An Elementary Process Model of Educational Expansion

We discuss first the simple demographic and resources processes introduced above. This simple model then is embedded in a dynamic model that characterizes the manner in which enrollments grow. Finally, we employ organizational dimensions of the three forms of educational organizations to derive a series of inequalities among the parameters of the models applied to each level (section II).

a. Demographic and resources effects. To a large extent, the educational career of an individual takes the form of a rigid processing, with a fixed sequence of steps. From an aggregate perspective, therefore, the total student enrollment at one level will set an upper limit to the number of suitable candidates for the next level and, thus, on the enrollment at that level at some later time point. For primary schooling, the upper limit is given by the size of the primary school-age population of the country.

The supply of qualified candidates is only one of the factors that are likely to determine enrollment in a given educational level. As we noted above, all the ingredients of education represent a cost of some kind. The price has to be paid by the community in one way or another, so that we expect that the total amount of wealth in the environment will also constrain enrollment at all three levels: the wealthier the country, the larger enrollments it can afford.

The two arguments can be summarized as follows. The joint action of the avail-

ability of candidates, or demand, and resource availability determines a ceiling on the expansion of each level of education. From an ecological point of view, the ceiling may be thought of as the *carrying capacity* of a population of organizations in the national environment. The candidates available, and the amount of resources in the system correspond, then, to the *parameters of the niche* of an organizational form. We do not assume that the size of a population of organizations at a given point in time always coincides with its carrying capacity. The actual degree of expansion of a population depends on dynamic considerations that are further discussed below.

If we let E_t^* denote the carrying capacity of some organizational form and C_t and R_t , the cohort and resource conditions, respectively, the model proposes that:

$$E_t^* = f(C_t, R_t). \quad (1)$$

We do not have any *a priori* knowledge of the functional form of (1). So for the present, we adopt the simplest possible form, a linear relationship:¹

$$E_{it}^* = \alpha'_1 + \gamma' C_{it} + \delta' R_{it}. \quad (2)$$

The parameter α'_1 summarizes the cultural, political and infrastructural conditions that affect the carrying capacity and vary from nation to nation, but are approximately constant over time for each nation.

b. Dynamic considerations. The creation and expansion of formal organizations requires the mobilization of resources. Such an effort requires time. Consequently, organizations cannot react instantly to

¹ The linear approximation has the defect that it implies non-zero enrollments when either C or R are zero. However, as we are considering the behavior of these systems far away from zero, we do not think this is a serious problem. Alternatively, we can specify that the relation in (2) is a power function and estimate the model under a logarithmic transformation. Our experience is that a log-log specification gives qualitatively similar results. We retain the linear specification since it leads to the simplest dynamic structure.

variations in their carrying capacities. Moreover, the speed of adjustment to a new level of demand/affordability is likely to depend on the structure of the organization, on characteristics of the environment, and on the magnitude of the required change. We can capture the most obvious features of these processes in a simple dynamic model.

As before, let E_t^* denote the carrying capacity of the environment for some form of organization and let E_t denote the existing degree of expansion. Then the growth of a system that responds to demand will depend on a comparison of E_t^* and E_t . In particular, we argue that:

$$\Delta E = \beta' (E_t^* - E_{t-\Delta t}) \quad (3)$$

where $\Delta E = E_t - E_{t-\Delta t}$, and Δt represents some time interval to be determined.²

According to (3), not only does the system expand when $E_{t-\Delta t}$ falls below E_t^* and decline when $E_{t-\Delta t}$ rises above E_t^* , but the speed of response is proportional to the distance from the *carrying capacity*. The speed of response parameter β' describes the characteristics of the organizations and the texture of the environment. When the individual members of a population of organizations are relatively adaptable and the environment offers many resources and little resistance (competition by other forms of organizations), β' will be close to one: the actual size E_t of the population fully adjusts to its carrying capacity E_t^* during the time interval Δt .³

² Models similar to equation (3) are often written as:

$$\Delta E = \beta'' \Delta t (E_t^* - E_{t-\Delta t}),$$

where β'' represents the response of the system during a unit time interval $\Delta t = 1$ (see, for example, Hummon et al., 1975). In the present context, we are not attempting to estimate the underlying continuous process. We choose to define $\beta' = \beta'' \Delta t$ and to focus on the coefficient β' , which permits us to formulate the dynamic properties of the model (e.g., the conditions of stability) in a simpler way. As Samuelson (1970: Appendix B) points out, the time variable in a difference equation can always be redefined so as to make the time interval Δt equal to unity.

³ The assumption that enrollment adjusts itself

Organizational inertia or environmental resistance will decrease β' .⁴ Therefore, the *responsiveness* parameter β' may be quite informative about the ecology of a population of organizations.

Finally, we make the obvious substitution of (2) into (3) to yield the full model:

$$E_t = (1 - \beta') E_{t-\Delta t} + \beta' a' + \beta' \gamma' C_t + \beta' \delta' R_t \quad (4)$$

Equation (4), a finite difference equation, can be rewritten as:

$$E_t = a + \beta E_{t-\Delta t} + \gamma C_t + \delta R_t \quad (5)$$

where $\beta = 1 - \beta'$, $a = \beta' a'$, $\gamma = \beta' \gamma'$, and $\delta = \beta' \delta'$.

In equation (5), a , γ and δ are compounded coefficients that incorporate the effects of demand or resources on equilibrium enrollment multiplied by β' , the measure of organizational responsiveness to the exogenously determined carrying capacity. Keeping γ' and δ' constant, the to E_t^* places constraints on the acceptable range of values of the coefficient β' , which has to be between 0 and 2. If β' is negative, the size of the population of organizations and its equilibrium value diverge over time. A β' greater than 2 implies that E_t exhibits oscillations of increasing amplitude over time. In the stable case, $1 < \beta' < 2$ entails oscillations of decreasing amplitude until $E_t = E_t^*$, while $0 < \beta' < 1$ corresponds to a monotonic convergence of E_t to E_t^* (Bialock, 1969: ch. 5; May, 1973: Appendix III).

⁴ One major mechanism of environmental resistance is competition with other forms of organizations. Competition between forms of organizations occurs when their respective carrying capacities depend on the same environmental variables, so that the expansion of one form decreases the carrying capacity, or maximum size, of others. Competition depends, therefore, on the relevant niche parameters. For example, the three levels of education do not compete for candidates, since their prospective students are likely to belong to very different groups, so an increase in enrollment at one level does not threaten the expansion of other levels. By contrast, they are likely to compete for *resources* (i.e., money), since the allocation of environmental resources for the expansion of one level of education are unavailable for other levels. In our simplified model of educational expansion, the net effect of competition is forced into the dynamic coefficient β , which is treated here as a purely phenomenological, descriptive parameter. We argue that competition decreases the speed of response of the populations involved.

higher β' , the higher the net effects of C_t and R_t on enrollment. Since we are mostly concerned in what follows with deriving and testing hypotheses on the value of γ and δ , which represent the net effects of demand and resources on *enrollment at time t*, rather than with γ' and δ' , the effects of these two variables on the carrying capacity E^* , we choose to reserve the expressions *cohort* and *resource effects* to refer to γ and δ , respectively. The coefficient β will be called the *inertia* parameter since it is a decreasing function of the responsiveness coefficient β' and indicates, therefore, the degree of organizational resistance to change. The larger β , the slower the adjustment of an educational level to its carrying capacity.

c. Empirical specification of the model. Equation (5) has the familiar form of a linear equation with lagged dependent variable. We require data at two or more time periods to estimate the model. In fact, we have observations on national enrollments at five-year intervals from 1950–1970 (UNESCO, 1971). We measure resources as gross national product in 1964 U.S. dollars (I.B.R.D., 1971). Following the earlier discussion, the size of the cohort, C_t , for each level of education is measured as the enrollment in the next lower level of education five years earlier. For primary schooling, the relevant cohort is the school-age population at that time. For a number of reasons, the measurement of cohorts for secondary and tertiary education are not ideal. The typical time spent in a level of education is usually different from five years, students may reenter the educational system after some interruption, etc. To attempt to correct for any resulting distortions, we add total national population to the models for secondary and tertiary education and primary enrollments to the model for tertiary.

The three empirical specifications of the general model of educational growth may be represented as follows:

$$\begin{aligned} \text{PRI}_t &= a_p + \beta_p \text{PRI}_{t-5} + \gamma_p \text{PRIPOP}_t + \delta_p \\ &\quad \text{GNP}_{t-5} + \epsilon_{pt} \end{aligned} \quad (6.1)$$

$$\begin{aligned} \text{SEC}_t &= a_s + \beta_s \text{SEC}_{t-5} + \gamma_s \text{PRI}_{t-5} + \delta_s \\ &\quad \text{GNP}_{t-5} + \xi_s \text{POP}_t + \epsilon_{st} \end{aligned} \quad (6.2)$$

$$\begin{aligned} \text{TER}_t &= a_T + \beta_T \text{TER}_{t-5} + \gamma_T \text{SEC}_{t-5} + \delta_T \\ &\quad \text{GNP}_{t-5} + \xi_T \text{POP}_t + \zeta_T \text{PRI}_t + \epsilon_{Tt} \end{aligned} \quad (6.3)$$

where PRI_t , SEC_t and TER_t denote the enrollments at time t in primary, secondary and tertiary education, respectively, POP_t (Taylor and Hudson, 1971) denotes national population at time t and PRIPOP_t denotes the size of the primary school-aged population at time t .

In equation (6), ϵ_p , ϵ_s and ϵ_T represent the combined effect on enrollment of variables omitted from the model. Alternative specifications of ϵ and their implications for estimation are discussed in section IV. An interesting theoretical feature of (6) is that the three equations contain *comparable* parameters of organizational significance: the inertia, cohort and resource coefficients (β , γ and δ , respectively). Since the model is defined on three populations of organizations that are assumed to differ systematically on the scales of complexity and unit-cost, we can compare these coefficients across populations and generate hypotheses relating their respective values with the assumed positions of the populations with respect to these structural criteria. In other words, from the organizational point of view, *the coefficients of the general dynamic model are the variables of substantive interest*. The next section is devoted to an elaboration of this theme and to the derivation of specific hypotheses.

II. Hypotheses

The general model described in section I reduces the growth of national enrollments to three main mechanisms. We first attempt to elucidate how the parameters that characterize these mechanisms would be expected to vary across populations of organizations that differ with respect to their degree of complexity and the amount of resources they require.

a. The inertia parameter. In each equation in (6), β is an *inverse* measure of the speed of adjustment to the carrying capacity. Therefore, β characterizes the degree of structural inertia of a population. A larger β means that population size is more dependent on the past, that it exhibits

a higher degree of rigidity with respect to exogenously induced pressures for a change in scale.

We argue that both a high degree of complexity and a high cost per unit lower the speed of adjustment of organizations and, therefore, increase the value of β . A highly complex and differentiated structure entails the need for a wide variety of specialized skills, roles and elements of material infrastructure. Not only does the organization compete more with others to mobilize choice ingredients in shorter supply and, thus, is less likely to fulfill its needs quickly, but the efficient coordination of the interdependent whole following growth is also more problematical. Conversely, once the organizational structure is created, the specialized components (people or things) are difficult to reallocate for some alternative use, and one would expect a high degree of resistance of the organization to decline as well as to growth.⁵ To take specific examples, such prerequisites of the educational process as libraries, schedules, laboratories, classrooms and adequate teaching and administrative bodies cannot be created and put together without a series of complex decisions and adjustments. The more differentiated the organization, the more complex the series of decisions involved in growth and the longer the adjustment time.

On the other hand, a high cost per unit limits the rate of organizational expansion in an obvious way. For the same level of success of an organization competing with others for environmental resources, a low-cost organization will expand more (in terms of units) than a high-cost one. To summarize both arguments, the speed of adjustment of the size of an organization is expected to be higher when the cost of an additional unit is low and when the organization can expand by the mere addition of relatively unspecialized segments

of human and material infrastructure. Thus we hypothesize: $\beta_P < \beta_S < \beta_T$.

b. The cohort effect. According to the general model embodied in equation (5), the coefficient γ associated with C_t is the product of γ' , the effect of the cohort of qualified candidates on E^* and β' , the coefficient of organizational responsiveness. If one assumes for a moment that γ' is the same for all three levels, it follows from the preceding discussion that the composite coefficient γ decreases in magnitude from PRI to TER. This is because the responsiveness coefficient β' is a decreasing function of the inertia parameter β , so that the discussion of paragraph (a) implies: $\beta'_P > \beta'_S > \beta'_T$.

It seems likely, however, that γ' itself is dependent on structural characteristics of the organization. Thompson (1967) argues that, in their efforts to approach bounded rationality, organizations attempt to seal off their core technology from environmental fluctuations. This protective function can be carried out by specialized boundary-spanning components through the buffering, leveling, forecasting and rationing of environmental demands. Thompson's argument can be extended, at the *population* level,⁶ by assuming that the protection requirements of organizations are some increasing function of the complexity and intensity (cost) of the core

⁵ For all the nations we are studying, enrollments increased over the period. Therefore, we do not address the likelihood that decline processes differ from growth processes for these forms of organizations (Freeman and Hannan, 1975).

⁶ This extension of Thompson's argument is one instance of an hypothesis that is more readily justified at the population level rather than for individual organizations. Considered separately, individual members of a population of organizations have available a variety of strategies, ranging from extreme exclusiveness to minimal boundary-spanning intensity. Whatever strategy is chosen presumably will depend in part on mechanisms of intrapopulation competition between organizations for membership and resources, so that one would expect the individual coefficients γ' to vary widely within the population. At the aggregate level of a population, by contrast, general constraints on the functioning of a given organizational form are likely to appear in a sharper light. From a deeper point of view, the issue is intimately connected with the problem of collective rationality (Hannan and Freeman, 1977): there is no guarantee that a course of action that is adaptive for a single organization will be optimal when many competing organizations adopt a similar strategy.

technology: *the more complex the core technology of an organization, and the more efforts and resources invested in each unit of input, the more selective the boundary-spanning components in charge of input.* In the educational context, such boundary-spanning activities manifest themselves in various guises: admission committees, entrance examinations, massive elimination after a short trial period within the organization, etc. In view of equation (5), it means that the carrying capacity of more complex and resource-intensive organizations will be less dependent on cohort size, so that $\gamma'_P > \gamma'_S > \gamma'_T$. Putting together the expected behaviors of the two component parts of the coefficient γ , $\beta'_P > \beta'_S > \beta'_T$ and $\gamma'_P > \gamma'_S > \gamma'_T$, with $\gamma = \beta' \gamma'$, we hypothesize that the estimated γ will decrease from PRI to TER: $\gamma_P > \gamma_S > \gamma_T$.

c. *The effect of resources.* The effect of environmental wealth is less easy to cast in terms of straightforward inequalities. δ , the coefficient to be estimated, is the product of the responsiveness, β' , and of δ' , the effect of resources on E^* . If one reduces equation (2) to its simplest form $E_t^* = \delta R_t$, the meaning of δ' can be expressed as: the average increase in the carrying capacity for enrollments due to an increase of one unit of resources in the system. However, we expect both the strength of the resource effect and the unit-cost to increase from PRI to TER. With the present model we cannot distinguish the two effects.

d. *Community of organizations and environmental resources.* Our analysis to this point involves comparison of three *populations* of organizations that differ on structural criteria. However, the three populations of organizations within a bounded system are clearly in a relationship of *sequential dependence* (Thompson, 1967): each level of education produces the input for the next. To that extent, the three populations interacting within the national boundaries constitute a *community* of organizations. We proceed to investigate the impact on the community of organizations of a major environmental constraint: the relative abundance of re-

sources. To this end, we introduce resources in a nonadditive way by estimating the equations (6) separately for poor and rich countries.⁷ This procedure leads to a series of additional hypotheses that take the form of pairwise comparisons of coefficients.

First, resource levels in the environment are likely to improve the capability of the three populations composing the community to adjust quickly to their respective carrying capacities: more resources in the system mean less competition between organizations for essential ingredients. Thus, for each level of education, the inertia coefficient β will be lower in rich countries (R) than in poor ones (P):

$$\beta_P^R < \beta_P^P; \beta_S^R < \beta_S^P; \beta_T^R < \beta_T^P.$$

Second, in an abundant environment, input fluctuations are likely to constitute a lesser threat for the core technology of an organization, since a temporary disequilibrium is more easily corrected by a reallocation of resources. Within a level of education, γ' is expected to be larger in rich countries. Since in addition the organizational responsiveness β' is also increased by wealth, the composite coefficient γ is expected to be larger in rich countries than in poor ones:

$$\gamma_P^R < \gamma_P^P; \gamma_S^R < \gamma_S^P; \gamma_T^R < \gamma_T^P.$$

This hypothesis can be readily translated into a property of the educational community as a whole. Since γ represents the effect of enrollment at one level on the size of the next, it provides a measure of the degree of sequential interdependence between the component parts of the national system of education. We argue that environmental wealth increases the interdependence of the three levels within the educational community.

Finally, analysis of the resource effect is somewhat more tractable within the

⁷ Nations are assigned to the poor or rich sample according to their position below or above the median GNP per capita measured in 1950, the earliest time point in the data. We exclude from the sample countries that were not independent in 1950.

community context. There are two reasons for expecting that δ' will be larger in poor nations. The first is a marginal return argument. When few resources are available, the major constraints on organizational growth are resource constraints. Thus, an increase in resources should have maximum impact in this situation. In richer environments, the bulk of causality presumably shifts to other potentially limiting factors. Second, unlike the case in the population level analysis, the unit-cost effect is in the same direction: a dollar of expenditures can purchase more educational services in a poor nation.

Notice that the coefficients δ , that are products of resource and responsiveness effects, are still indeterminate in sign. We argue that the resource effect is larger in poor nations but that responsiveness is higher in rich nations. Thus we must compute δ' explicitly.

III. Methodology

a. Pooled cross-section and time series analysis. Rather than estimate (6) separately for each of the four 5-year lags, we pool all of the data into a single model. This design, discussed extensively by Nerlove (1971) and Hannan and Young (1977), permits us to deal satisfactorily with an estimation problem that plagues almost all sociological panel analyses: autocorrelation of disturbances. In motivating (2), we pointed to the relatively constant features of national cultural, social and political organization that affect educational expansion. Since these features are not measured here, they are forced into the disturbances in (6). Since they presumably operate in every period, the disturbances are correlated over time and with the lagged dependent variables. Consequently, ordinary least-squares estimators applied to (6) are biased and inconsistent. If the autocorrelation of disturbances is due only to the constant nation-specific effects (i.e., $\epsilon_{it} = \mu_{it} + v_{it}$, where the v_{it} are well-behaved random disturbances), two strategies of estimation applied to the pooled model yield consistent and asymptotically efficient estimators. The first, LSDV (least-squares with dummy vari-

ables) treats the μ_i as fixed effects and calculates pooled within-nation regressions. The second, MGLS (modified generalized least-squares), treats the μ_i as random effects. Their variance contributions are to be estimated under the assumption that the μ_i have constant variance. When the constant variance assumption holds, MGLS has better small sample properties (Nerlove, 1971; Hannan and Young, 1977). However, since we are uncertain that the constant variance assumption is appropriate to these data, we report results from both approaches.

b. Heteroscedasticity. When the units of observation differ greatly in size, the random portion of the disturbances are unlikely to have constant variances (see the discussion in Freeman and Hannan, 1975). In fact, preliminary analysis of these data indicated that the absolute values of disturbances increased sharply with size. Therefore, we introduce a generalized least-squares correction, namely, weighted least-squares. However, implementing weighting in the pooled model is complicated. We have shifted from the Nerlove-type estimators most usually used to those proposed by Henderson, Sr. (1952; 1963; see also Henderson, Jr., 1971) which permit us to construct two estimators that simultaneously control for both nation-specific factors and heteroscedasticity.⁸ They parallel the two approaches introduced above. We label the fixed effects estimator WLSDV (weighted least-squares with dummy variables) and the random effects estimator WGLS (weighted generalized least-squares). Both are consistent and asymptotically efficient under the stated assumptions. A justification for this procedure and an algorithm are presented in Nielsen (1974).

IV. Results

We begin by presenting estimates of (6) for the population and community level hypotheses. Then we calculate estimates of the underlying dynamic model.

⁸ The weighting factors are PRIPOP_i in the PRI_i equation and POP_i in equations for SEC_i and TER_i.

a. Cross-population analysis. We start by investigating the hypothesized ordering of inertia and cohort effects in (6) across the three populations of organizations. Table 1 gives the relevant results for the two estimators and two samples (rich and poor nations). Consider first the inertia effect. For both estimators and both samples, we find the hypothesized effect: the estimated inertia parameter increases from primary to secondary to tertiary. For example, the WLSDV estimates are .169, .694 and .872 for primary, secondary and tertiary in rich nations and .552, .747 and .935 in poor ones. This result lends support to our theoretical expectation: at the population level, more complex organizations, with a higher unit-cost, adjust more slowly to their carrying capacity.

The hypothesis concerning the cohort parameter is that it should decrease from primary to tertiary. This hypothesis also fits the data perfectly. Therefore, more complex and costly educational organizations tend to incorporate a smaller fraction of the supply of qualified candidates.

We argued that the dimensionality of the linear resource parameter made its meaning ambiguous. Nevertheless, it is interesting to examine the empirical results to see if the coefficients exhibit some systematic pattern across educational levels. The resource coefficient for SEC enrollments is the highest for all four sample-estimator combinations. This seems to suggest that the two effects in opposite directions of complexity and cost on the resource parameter indeed take place in reality. The low coefficient of primary would then be explained by a low "dependence" on resources, the low tertiary coefficient by a high "cost" effect in the opposite direction while the higher resource parameter of secondary would result from a combination of more dependence on resources not yet offset by a parallel increase in cost. This interpretation is, of course, ad hoc, but the empirical results strongly suggest the existence of a curvilinear relationship.

b. Cross-community hypotheses. To test the effect of the abundance of the environment on the inertia, cohort and resource parameters, we compare estimates for rich

and poor countries. For example, by the WLSDV method the inertia parameter of primary is estimated as .169 for rich countries and .552 for poor ones; the inertia coefficients are .694 and .747 for secondary and .872 and .935 for tertiary. The same pattern holds for the WGLS estimates. Thus, our first community hypothesis is confirmed: the inertia parameter tends to be lower in wealthier environments.

The cohort coefficients are analyzed by similar techniques. For both estimators, the postulated inequality holds: for each educational level the cohort effect is higher in rich environments than in poor ones. That is, in wealthier countries the educational system is more responsive to the demographic pressure of the pool of qualified candidates.

The last set of hypotheses concerns the effect of the abundance of the environment on the resource parameter of the educational system. Recall that the resource effect is defined on δ , the effect of R_t on E^* , and that δ is a composite coefficient, the product of parameters δ' and β' that are expected to be found in reverse orderings when compared across environments. The situation, however, can be approached through the following *a fortiori* argument: if δ is larger for poor countries, then δ' must be larger also, since the smaller responsiveness coefficient β' would tend to diminish the value of δ and obliterate the difference between poor and rich countries. Keeping this possibility in mind, we compare the estimates of δ across the two samples. For the first time, we encounter substantial disagreement between estimators. For WLSDV, the resource effect is larger for poor nations for each level of education. However, exactly the reverse pattern holds with the WGLS estimates. We have not been able to determine why this difference arises. It may have something to do with small samples properties of the WGLS method in that unweighted GLS estimates (not reported here) agree with those of WLSDV. Clearly, this matter deserves deeper study.

c. The determination of carrying capacities. We have managed, so far, to

Table 1. Estimates of Coefficients of Model (6) *

Dependent Variable	Sample	Method	Independent Variables							R ²	N
			PRI _{t-5}	SEC _{t-5}	TER _{t-5}	GNP _{t-5}	POP _t	PRIOPOP _{t-5}	CONSTANT

		WGLS	.036 (.020)	1.119 (.082)		.029 (.062)	.023 (.015)		-23.57 (48.76)	.948	29
TERTIARY Enrollment:	Rich Nations	WLSDV	.018 (.015)	.035 (.019)	.872 (.112)	.035 (.014)	-.016 (.045)		0	.899	29
		WGLS	.017 (.008)	.013 (.011)	1.160 (.068)	.013 (.005)	-.023 (.010)		-.96 (4.72)	.972	29
	Poor Nations	WLSDV	-.023 (.009)	.002 (.024)	.935 (.024)	.040 (.094)	.068 (.019)	.017	0	.832	29
		WGLS	.005 (.004)	.012 (.008)	1.165 (.061)	.005 (.011)	-.000 (.003)		-4.42 (6.57)	.958	29

* Standard errors in parentheses.

verify most of the propositions of section II without explicitly computing the parameters of equation (2) for the carrying capacity: γ' and δ' . These coefficients, however, can be easily recovered from equation (5): β' is first computed as $1-\beta$, and then γ' and δ' as γ/β' and δ/β' , respectively. Given our results, these calculations are meaningful only for the WLSDV estimates for reasons we discuss below. The calculations are reported in Table 2. Across the levels of education, both β' and γ' exhibit the expected decrease from PRI to TER and the behavior of δ' remains curvilinear with the highest resource effect in the SEC equations. The rich-poor comparisons are also all in the expected direction (the one exception is γ' for PRI, where the effect for poor nations is slightly larger). More important, we finally get a clean test of the community-level resource hypothesis. As we had predicted, the resource effect for each level of education is larger for poor nations.

We could not make similar calculations from the WGLS estimates because the estimated β exceed unity in four of the six equations. This implies that the responsiveness parameter is negative. A negative responsiveness parameter implies substantively meaningless dynamics. This problem

likely stems from any combination of three complications: (1) the functional form of the dynamics may not be appropriate, especially for more complex organizations (the problem seems worst for tertiary education); (2) the hypothesis that the transitory portion of the disturbances of (6) are not autocorrelated may be wrong; (3) the constant portion of the disturbances in (6) may not have constant variance. Each of these issues demands further study. It is particularly important that the dynamic structure be clarified further. In the meantime, our results must be considered a first approximation.

V. Discussion and Conclusion

This paper focuses on the aggregate size of populations of organizations. This point of view enabled us to propose a simple dynamic model of educational growth, independent from individual variations in organizational strategies due to mechanisms of intra-population competition (see footnote 6). Since the model could be specified for three populations of organizations (the primary, secondary and tertiary levels) within two types of environments (rich and poor), we could meaningfully compare general mechanisms of change (inertia, cohort effect and dependence on resources) across populations and environments.

The results confirm, on the whole, our population ecology model of organizational growth. The maximum size of a population of organizations within a bounded environment is determined by the *carrying capacity* of the environment for a particular organizational form. In our simplified model of educational expansion, we specified the carrying capacity as a function of two *niche parameters*: the supply of qualified candidates and the amount of resources in the environment. An immediate goal for further research consists in identifying other parameters of the niche of an organizational form (e.g., political and cultural factors). A population of organizations, however, cannot react instantly to an expansion or contraction of the carrying capacity of the environment

Table 2. Estimates of Parameters of the Dynamic Model (WLSDV)*

		Rich Nations	Poor Nations
Responsiveness:			
$\hat{\beta}' (=1-\hat{\beta})$	PRI	.831	.448
	SEC	.306	.253
	TER	.128	.065
Effect of Cohort on Equilibrium:			
$\hat{\gamma}' (= \hat{\gamma}/\hat{\beta})$	PRI	1.291	1.304
	SEC	.899	.419
	TER	.273	.031
Effect of Resources on Equilibrium:			
$\hat{\delta}' (= \hat{\delta}/\hat{\beta})$	PRI	-.128	.324
	SEC	.621	.929
	TER	.273	.615

* Calculated from estimates in Table 1. See text for explanation.

because of both the inherent structural inertia of individual organizations and competition between populations for resources and membership. In our model, structural inertia and the effect of competition are lumped together in the inertia parameter β . We showed that this coefficient, and the dynamic mechanisms it represents, could be meaningfully compared across populations and environments. Further work should attempt to analyze the process of growth by modeling explicitly the mechanisms of competition.

SCIENTIFIC PRODUCTIVITY AND THE REWARD STRUCTURE OF SCIENCE*

BARBARA F. RESKIN

Indiana University

American Sociological Review 1977, Vol. 42 (June):491-504

Regression analyses of longitudinal data for a probability sample of chemists provide estimates of the causal links between chemists' predoctoral training, early productivity, recognition and organizational context and productivity at the end of the first postdoctoral decade. After identifying certain methodological problems involved in using Science Citation Index citation counts to assess the effects of collegial recognition on later productivity, I report tests of several hypotheses proposed to account for scientists' conformity to productivity norms. Apart from the calibre of the Ph.D. department, measures of socialization have no direct effect on decade productivity. Early productivity and collegial recognition do contribute to decade productivity, but the strength of their effects varies by the research orientation of the first employer: early productivity is more important for those employed in universities, whereas collegial recognition is particularly important for chemists in contexts that do not stress scholarly publication.

Scientific research is fraught with difficulties which are not characteristic of most professional work. Scientists must choose research questions that are solvable yet nontrivial, must apply disciplined and creative efforts to intractable problems, must convince others that their results are valid and valuable and must tolerate high levels of competition that may deprive them of the ultimate reward of recognition from the scientific community (Merton, 1957; Hagstrom, 1974). Furthermore, scientists must work without the structural supports for role performance that many other professionals take for granted. For example, scientists' services are not subject to the high public demand that structures the work of free professionals; they must schedule their own work and that of their assistants. Rarely subject to regular supervision, sci-

entists also lack the short-run incentives that rewards for daily performance provide. While they are powerful sanctions in the long run, promotion, tenure and salary raises are probably not especially effective in maintaining day-to-day conformity to productivity norms. Moreover, many scientists have nonresearch obligations (teaching, administration) that do have deadlines, are subject to positive and negative sanctions and, thus, can divert them from their less structured research work.¹

Several social-control mechanisms ensure that some scientists undertake the uncertain task of original research. These include selective recruitment of highly-talented individuals to scientific careers (Harmon, 1965), intensive research training (Ben-David, 1971:141-2), socialization to norms emphasizing research and publication (Hagstrom, 1965:10) and rewards for productivity (Merton, 1957; Hagstrom, 1965). Some observers of science have stressed the intrinsic psychological rewards of scientific achievement, but the former are probably

* I am grateful to Lowell L. Hargens, Paul D. Allison, Warren O. Hagstrom, Daryl Chubin, Lindsey R. Harmon, Nicholas C. Mullins, Edward Kick and an anonymous reviewer for their helpful comments on previous drafts of this paper. Any errors are, of course, solely my responsibility. I am indebted to Carolyn Mullins for editorial assistance and Paul T. Melevin, Debi Dennis and Antonio A. Arbuto for assistance with data collection, which was partly supported by a Faculty-in-Aid from Indiana University.

¹ Stinchcombe (1966:30) suggested strategies for overcoming these obstacles, but their general effectiveness is still unproved (Hargens, 1977).

not sufficient for most scientists without the professional rewards that usually accompany them. Extrinsic rewards—formal and informal recognition (Hagstrom, 1965); material rewards, such as positions and research resources; and, less frequently, prizes and honors (Zuckerman, 1970:237)—appear to be the major source of social control in science. Yet, in spite of these rewards and their effectiveness for some, many scientists do no original research after leaving graduate school and rarely or never publish (Price, 1963:47). Apparently, the scientific reward-structure, while perhaps sufficient to maintain scientific progress (Cole and Cole, 1972), is not particularly effective in maintaining conformity to professional norms at the individual level. Several hypotheses (reviewed below) have been proposed to account for this variation in scientists' productivity. This paper reports tests of some of them, using data for scientists from a single discipline, chemistry.

DETERMINANTS OF SCIENTIFIC PRODUCTIVITY

Until recently, most studies of scientific productivity were done by psychologists interested in either creativity (Eiduson, 1962) or organizational characteristics that maximize productivity (Taylor and Barron, 1963; Pelz and Andrews, 1966). The former studies, which emphasized the role of personal characteristics such as intelligence, motivation or other personality traits (Roe, 1952), have added little to our understanding of the determinants of productivity. Despite its intuitive appeal, measured ability has yet to distinguish between more and less productive scientists (Taylor and Barron, 1963; Bayer and Folger, 1966:389–9; Cole, 1974:40). Nor have hypotheses about the impact of motivation on productivity been supported (Pelz and Andrews, 1966:190–1). For example, the "sacred-spark" hypothesis (Cole and Cole, 1973:114), which holds that an inner drive compels some scientists to do research even in the absence of rewards, has been untested, largely because of measurement difficul-

ties. Nevertheless, it has been proposed as an alternative explanation for productivity differences unexplained by reinforcement (see, for example, Allison and Stewart, 1974). The Coles (1973:71) have also suggested that sheer stamina may play an important role in scientific productivity, but the relationship between one measure of stamina—number of hours worked per week—and scientific output is weak (Fulton and Trow, 1974:62; Hargens, 1977).²

Socialization

Because some aspects of professional socialization are public, certain facets of socialization are more amenable to measurement than the professional commitment it is thought to engender. Thus, while we lack data that permit exploring the links between socialization, scientific commitment and conformity to professional norms, researchers have studied the relationship between scientists' socialization and their productivity. Aran and Ben-David (1968), for example, found that "resocialization" into the international scientific community was associated with both increased and "more specific" publications among Israeli medical researchers. Reported links between scientists' later success and their sponsors' eminence (Crane, 1965; Zuckerman, 1967) or the calibre of their Ph.D. departments (Bayer and Folger, 1966:388; Hargens and Hagstrom, 1967; Cole, 1974) provide indirect evidence for the effect of socialization, but these associations may also reflect a selection process wherein graduate students' talents are roughly matched with the calibre of their doctoral sponsors or the quality of their Ph.D. departments. Measures of scientists' predoctoral ability are necessary to sort out these two processes.

² The empirical support for relationships between other research practices and productivity, while mixed, has been generally negative (Gaston, 1970; Simon, 1974). Variation in four research practices (patterns of collaboration, deadlines, number of projects simultaneously pursued, and number of hours spent on research) accounted for only 5% of the variation in university scientists' output (Hargens, 1977).

Reinforcement and the Accumulation of Advantages

While socialization and professional commitment undoubtedly influence conformity to productivity norms, neither are sufficient to maintain conformity without a reward structure that reinforces appropriate role behavior (Hagstrom, 1965:12, 21). Institutional features of science provide a variety of reinforcers such as the personal satisfaction derived from completing creative work (or, in Guston's [1973] terms, from "partaking of the charisma of science"), collegial recognition expressed through the acceptance of research papers for publication or citations to published work, material rewards such as research grants and the conferral of formal honors (Hagstrom, 1965:28). Given its public nature, formal collegial recognition should be a particularly effective reinforcer. Using citations as a measure of collegial recognition, the Coles (1973:110-5) found some support for the reinforcement hypothesis among university physicists, thereby simultaneously demonstrating the utility of a reinforcement approach and the potential value of more fully specified reinforcement models. Their accumulative-advantage hypothesis (Cole and Cole, 1973:119-22) elaborates the reinforcement hypothesis to take into account the feedback relationship between productivity, recognition and resources. Briefly, collegial recognition of published work demonstrates a scientist's merit to those who distribute professional resources (appointments, promotions, grants, research assistance), which not only reinforce past productivity but also facilitate future productivity. Through this process, successful scientists accumulate rewards that lead to even greater productivity. The "Matthew effect" (Merton, 1968) refers to such disproportionate recognition of the contributions of well-known scientists. Allison and Stewart (1974) hypothesized that the process of accumulative advantage would give rise to an improved fit between resources, productivity and recognition with scientists' increasing age. Their findings for academic scientists were consis-

tent with predictions derived from the reinforcement and accumulative advantage hypotheses. While these studies are highly suggestive, they did not separate the effects of ability and socialization from those of reinforcement. Moreover, they were limited to academic scientists. But reward systems are not uniform throughout the scientific community and their effects may depend on scientists' location. Thus, in order to understand the determinants of conformity to productivity norms, we must consider organizational contexts with varying reward structures.

Organizational Contexts and Rewards

Theoretically, organizational context should directly affect scientists' productivity and specify the effects of other variables. Organizations that value the production of knowledge should reinforce such behavior with professional rewards that will facilitate future research (Hagstrom, 1965:39). Organizations committed to other goals will rely on organizational rather than professional incentives, such as promotion to administrative jobs, to maintain performance (Kornhauser, 1962:131; Hagstrom, 1965:37).

The relationship between setting and productivity is well established (Pelz and Andrews, 1966:6; Fulton and Trow, 1974:46; Hagstrom, 1968) and, as expected, publication is less important for promotion in nonresearch-oriented organizations (Meltzer, 1956). Of course, the association between context and output also might be due to selective recruitment, and this alternative must be considered. In either case, the hypothesized impact of collegial recognition on scientific productivity may vary depending on the values of the employing organization. While it may be attenuated among scientists working in contexts not oriented toward the production of scientific knowledge, scientists in such settings who do publish may be even more responsive to mechanisms that symbolize their connection to the larger scientific community.

THE PRESENT STUDY

The research reported here extends previous work in several ways. First, unlike most studies which used cross-sectional data, this analysis employs longitudinal data for the sample members' first postdoctoral decade, so the time order of important events is clear. Second, previous tests of the reinforcement hypothesis were restricted to that minority of scientists employed in universities (Office of Scientific Personnel, 1967:115).³ While the latter do write most scholarly articles (Krause, cited in Hagstrom, 1965:38), by sampling all scientists who are *qualified to do research* (i.e., Ph.D.s) variation in productivity is increased and the impact of organizational context can be assessed.⁴ Third, data on predoctoral ability and educational background provide controls for some aspects of selection and socialization.

DATA AND MEASURES

This research is based on the careers of a systematic random sample of 238 doctoral chemists who obtained their Ph.D.s from U.S. universities between 1955 and 1961. The sample was drawn from the American Chemical Society's biennial *Directory of Graduate Research (DGR)*, which also provided the names of the chemists' doctoral sponsors. Sample members' educational and career histories were obtained from the 11th and 12th editions of *American Men and Women of Science (AMWS)* and from mailed questionnaires for chemists not included in *AMWS*. These sources ultimately yielded professional histories for 95% of the sample,⁵ including data on length of doctoral

study, and employment setting at the beginning and end of the first postdoctoral decade. In order to examine the impact of context on productivity, I classified organizations in terms of research orientation with two dummy variables: university employment versus all other contexts,⁶ and employment in a research-oriented context (university, government laboratory or nonprofit research institute) versus all other contexts.

Productivity and Recognition Measures

For this study, unpublished work, books and patents were excluded from the productivity measure.⁷ Data on productivity came from *Chemical Abstracts (CA)*, American Chemical Society) and *Science Citation Index (SCI)*, Institute for Scientific Information).⁸ Both sources list articles for all authors of multiple-authored papers. Productivity was observed for three time-periods: prior to the Ph.D. ("predoctoral productivity"), during the three-year period following the Ph.D. beginning with the Ph.D. year ("early productivity") and during the chemists' ninth and tenth postdoctoral years ("decade productivity").

Collegial recognition is usually measured with citation counts (Bayer and Folger, 1966; Cole and Cole, 1971), available in the *SCI* since 1961. *SCI* attributes citations to first authors only. While this procedure apparently does not bias estimates of recognition for established scientists (Hagstrom, 1968; Cole and Cole, 1971), counts for scientists who are disproportionately junior authors will underestimate the total citations to their published work and, presumably, the recognition they experience (assuming, of course, that junior authors feel as rewarded by citations or receive as many rewards for

³ For example, in chemistry, only one-seventh of the Ph.D.s in the late 1950s and early 1960s began their careers in university positions.

⁴ This design also avoids the problem that inter-organizational mobility poses for studies restricted to university scientists.

⁵ Nonrespondents (i.e., those for whom career data were unavailable) and respondents did not differ significantly on either early productivity or their number of early citations, but nonrespondents had significantly fewer decade publications. This association is partly an artifact of the way chemists not included in *AMWS* were located (see Reskin, 1973: Appendix 1). Given the high response rate, this difference should have little effect on the results.

⁶ Academic institutions shown in the *DGR* as granting advanced degrees in chemistry are coded as universities; all others are coded as colleges.

⁷ Books represent a very small part of sample members' publications. Excluding patents, however, does underestimate an important form of the productivity of industrial chemists.

⁸ Article counts came from *CA* through 1964; after 1964, they were taken from *SCI*. I did not use available *SCI* data for 1961 or 1964 because these first two volumes underreport sample members' publications.

them as do senior authors). New Ph.D.s are probably more likely than mature scientists to coauthor papers and more likely to be junior authors.⁹ Thus, citation counts may systematically underestimate the amount of recognition young scientists receive.¹⁰ Ideally, one would identify the first authors of chemists' junior-authored papers and add their citations to the junior authors' totals, but this was not feasible. As an alternative, I took authorship order into account in the analyses reported below. The number of citations to the chemists' early work that were shown in the 1961 or 1964 volumes of *SCI* indicate *early recognition*.¹¹ All productivity and recognition measures were standardized by the chemists' Ph.D. year to adjust for variation in *CA* and *SCI* coverage over time.¹²

Ability and Socialization Measures

Controls for predoctoral ability are desirable both to rule out selection as an alternative explanation for apparent socialization or context effects and to specify the regression equations as fully as possible. Since intelligence-test scores are not related to scientific productivity, they are not a desirable measure of predoctoral ability. But scientists do vary in their propensity to do publishable research; and this trait, which should appear rather early in chemists' training, is fairly stable over time (Hargens et al., 1976). Thus, measures of chemists' predoctoral research output should reflect this propensity. Predoctoral publication has been shown to be related to later productivity among sociologists (Clemente, 1973:415).

⁹ Sample members were junior authors in 44% of their pre-Ph.D. publications and in 35% of the articles published during their Ph.D. year and the two following years. They collaborated with their sponsors on about half of the latter articles.

¹⁰ Previous studies (e.g., Cole and Cole, 1973) have failed to take this problem into account.

¹¹ *SCI* did not publish citation data before 1961 or in 1962 and 1963; thus, I used 1961 citations for 1955 to 1958 Ph.D.s, 1964 citations for 1959 to 1961 Ph.D.s.

¹² Since this procedure precludes interpreting the regression coefficients in terms of the increment in later articles associated with each additional early article or citation, only standardized regression coefficients are reported.

However, simple pre-Ph.D. article counts may be biased in two ways. First, coauthored publications may reflect substantial contributions from more experienced faculty members, so I counted the number of single-authored predoctoral publications. Second, the number of predoctoral publications should reflect the length of time in which predoctoral publication could occur, so that the duration of doctoral study (a second indicator of predoctoral ability discussed below) should be positively related to the number of predoctoral publications. To control for this, I regressed publication counts on the length of doctoral study and used the residuals as a measure of predoctoral ability.

An additional indicator of predoctoral performance is the duration of doctoral study. The negative relationship between time taken to complete the Ph.D. and later professional success observed in several disciplines (Hagstrom, 1971:386; Clemente, 1973:415; Reskin, 1973) has been interpreted as the effect of ability or motivation (Folger et al., 1970:265).

I measured three aspects of socialization. The productivity of the chemists' doctoral sponsors during the period the chemists were graduate students should reflect the socialization that sponsors provide through direct tuition and as role models. Actual student-sponsor collaboration should reflect additional professional guidance beyond that involved in routine supervision. Although faculty differ in their propensity to share responsibility for their students' published research, presumably they have a greater degree of involvement in work which bears their names. Finally, a postdoctoral fellowship may provide additional socialization. Fellowship recipients often study at institutions more prestigious than their Ph.D. departments (Berelson, 1962:127) and with more eminent sponsors (N.A.S., 1969:71), often with the goal of acquiring additional skills (N.A.S., 1969:64-5). And the experience pays off: former fellows are more productive than are nonrecipients (Folger et al., 1970:267; N.A.S., 1974; Reskin, 1976). Sponsors' productivity is the number of articles attributed to the sponsors during the four-year

period ending with the chemists' Ph.D. years minus the number of student-sponsor coauthored papers (the second socialization measure). Postdoctoral fellowships (coded 0 for none, 1 for any) were reported in *AMWS* or the biographical questionnaire.

The calibre of the Ph.D. department (measured by rankings in Cartter, 1966) in part measures the quality of graduate training and is associated with productivity. But this association may also reflect the ability of better-quality departments to recruit the most talented students. Studies that simultaneously considered the impacts of ability and the calibre of the Ph.D. department support interpreting the latter as an indicator of ability (see Bayer and Folger, 1966:388-9; Folger et al., 1970:264; Cole, 1974:70); but without sound measures of ability, the implications of the department-calibre/productivity relationship cannot be resolved.

Finally, productivity varies by specialty within chemistry (with organic chemists publishing less; Blume and Sinclair, 1973:133). Specialty was controlled with a dummy variable with organic chemists coded 0, all others coded 1.

RESULTS

Distribution of Publications

The chemists' distribution of publications is consistent with our knowledge that a small proportion of scientists contribute most publications (Price, 1963:45): 7.5% of the sample members did not publish during their first postdoctoral decade, and an additional 11% published only one article. Only 15% of the sample members authored half of the almost 2,000 articles these scientists published,¹³ and, with one exception, no more than 40% published an article in any year. The Gini index provides a measure of the inequality in the distribution of publications. For the eleven-year period beginning with the Ph.D. year, the Gini indices are remark-

ably stable, about .76, indicating pronounced inequality in article productivity. These values are substantially higher than those Allison and Stewart (1974:600) report, reflecting the greater heterogeneity of my sample.¹⁴

These results lead us to the question addressed in the remainder of this paper: what accounts for the differential productivity of the chemists surveyed? Before reporting analyses for the chemists' productivity at the end of their first professional decade, I present the results of multiple-regression analyses for early postdoctoral productivity and early recognition.

Early Productivity

Regression results in equation (1) of Table 1 show some of the expected effects of predoctoral ability and professional socialization on early postdoctoral productivity. While length of doctoral study did not affect early productivity, the number of single-authored predoctoral publications showed a significant independent effect. The direction of its impact varied with the calibre of the Ph.D. department: for chemists from low-calibre departments (those unranked by Cartter or classified as "not sufficient" or "marginal"), single-authored predoctoral publications were positively related to early postdoctoral output; for chemists from more highly ranked departments, the relationship was negative.¹⁵ This specification by the calibre of the Ph.D. department is reflected by the significant positive main effect of predoctoral publications and the negative effect of the interaction term. Students and faculty collaborated more often in better departments than in low-prestige departments, and those students from high-calibre departments who publish alone may do so for want of faculty coauthors.

¹⁴ The indices for my sample show neither increasing nor decreasing inequality over time. This discrepancy with Allison and Stewart's (1974:600) results is due to the substantially longer period their synthetic cohorts cover.

¹⁵ These findings are based on separate regression analyses for each of Cartter's major department-prestige categories, not presented here.

¹³ Because of my restricted period of observation, this figure is higher than Price's (1963:45-6) estimate of 6-10%; some of the chemists in my sample will never publish after their first postdoctoral decade.

Table 1. Regression Equations for Early Productivity, Early Recognition, and Decade Productivity *

Independent Variables	Standardized Regression Coefficients

* Except for a single indicator of each theoretically relevant control variable, variables that were not statistically significant at the .05 level were excluded.

* Coefficient at least twice its standard error.

† Omitted in favor of an alternative measure. See text for bases for selecting alternative measures for particular equations.

Two of the socialization indicators significantly affected early productivity, but the effect of one—sponsors' productivity—also depended on the calibre of the sample members' Ph.D. departments. In low-calibre departments, working with a productive sponsor *reduced* the chemists' own early productivity, whereas in "distinguished" departments, having a prolific sponsor increased early postdoctoral output (see footnote 15). This interaction is reflected in the significant negative main effect of sponsors' productivity and the significant positive product of the former and Ph.D.-department calibre shown in equation (1). Assuming a moderately good fit between faculty talents and departmental calibre, faculty at top departments would be better researchers and have more to offer their students than equally productive staff at

low-prestige departments. Productive faculty at lower-quality institutions might also be skeptical about the value of investing time in training students whom they do not expect to pursue research careers.

As predicted, the chemists benefited from predoctoral collaboration with their sponsors. While this result may reflect socialization, an alternative explanation is possible. Collaborations among chemists during graduate school may lead to postdoctoral coauthored articles. To test this alternative, I included the number of articles the chemists coauthored with their sponsors during the first two post-Ph.D. years in the regression equation. While the standardized coefficient for predoctoral collaboration dropped slightly (from .33 to .29), it remained an important predictor of early productivity.

Any socialization resulting from a post-

doctoral fellowship should not be reflected in early productivity because the interval between completing the postdoctoral fellowship and the time remaining in the early-productivity measure was too short for any effect of an award to be reflected.¹⁶

Apart from the interactions described above, the calibre of the Ph.D. department was unrelated to early productivity. (The negative sign for its regression coefficient results from including the two Ph.D.-calibre interaction terms in the equation and has no substantive meaning.) More surprising was the failure of either of the measures of first employment setting to show the expected positive effects.¹⁷ The zero-order associations between setting and productivity, although small ($r = .11$ for universities; $.16$ for all research-oriented organizations), were significant, but their partial association disappears because the same background variables that affect early productivity are important determinants of working in these contexts.

Early Recognition

The analysis of early recognition provides a partial test of the accumulative-advantage hypothesis. Scientists may accumulate advantages by acquiring training or credentials that enhance either the quality or the visibility of their work. The advantages may elicit greater collegial recognition (in itself reinforcing) and may also attract additional resources that will facilitate future performance. For example, a purported benefit of the "Matthew effect" (Merton, 1968) for young scientists is the increased visibility resulting from collaborating with established scientists. Even without actually collaborating, students of well-known scientists may receive disproportionate recognition.¹⁸

¹⁶ In addition, for 29% of the postdoctoral fellows the award was subsequent to the period covered by the early-productivity measure.

¹⁷ The results for employment in a research-oriented organization are similar to those shown in equation (1) for university employment.

¹⁸ This assumes that this ascribed status is known to potential citers; acknowledgements sometimes reveal such information. Of course, such a pattern would also occur if they did better work.

Young chemists who come from prestigious Ph.D. departments or who obtain desirable university jobs may also accumulate advantages if their institutional affiliation listed on their articles elicits increased citations. I tested for such advantages by examining the effects on early citations of the interaction of early productivity and (a) collaborating with one's sponsor, (b) collaborating with a particularly productive sponsor, (c) coming from a prestigious Ph.D. department and (d) working in a university.

The regression equation for early citations is shown in equation (2). Although predoctoral publication was not related to early recognition, the more quickly the chemists completed their training, the more often they were cited early in their careers. The calibre of their Ph.D. department and a postdoctoral fellowship were also positively related to early citations. Their sponsors' productivity did not affect the frequency with which the chemists were cited, and the significant zero-order effect of coauthoring papers with their sponsors during graduate school ($r = .18$) was mediated entirely by its impact on early postdoctoral productivity. However, before concluding that collaboration had no direct effect on recognition, we must ask whether order of authorship specified the relationship. Given the underestimation of citations to junior authors, the expected collaboration effect should hold only for chemists who were primarily senior authors. In fact, results of an analysis of covariance not shown here revealed no significant difference between chemists who were exclusively junior and exclusively senior authors; in neither of these subgroups did collaboration contribute significantly to recognition.

Since cited scientists first-author at least one article (except for a few citations to unpublished work), the strong effect of the number of first-authored articles published between the Ph.D. year and the second postdoctoral year ($b^* = .403$) is expected.

Although employment context had no simple effect on citations, the return in citations to early publications was significantly greater for chemists whose first

jobs were in universities. Their work may have been more useful than that produced by nonuniversity chemists, or their institutional affiliation may have influenced readers' judgments. None of the other product terms included to test accumulative advantage was statistically significant, and they are not included in equation (2). While the significant effect for the employment-context/early-productivity interaction term is consistent with the accumulation of advantages to scientists who were initially well placed, it would also follow from a selection process in which potentially better researchers who produced work deserving greater recognition were hired by universities. Lacking an independent measure of the quality of publications (citations themselves are usually used for this purpose), I can not choose between these interpretations. Still, several measures of ability were controlled in the regression procedure. At the very least, these results do not rule out the possibility of accumulative advantage with respect to the first-job setting.

Decade Productivity

By the end of their first postdoctoral decade, sample members had had ample time to establish research programs, publish results and build at least minor reputations. Thus, I observed their productivity at this point, seven years after early productivity was observed and three to six years after early citations were counted. The lag is small enough for any effects of early recognition to persist, but enough time elapsed so that any independent effect of early productivity would constitute support for the sacred-spark hypothesis. Mobility during the first postdoctoral decade should lead to an improved fit between the chemists' productivity and employers' requirements, so organizational context at the end of the decade should mediate the effects of early productivity on later productivity. The decade-productivity regression results (see equations [3a] and [3b]) provide some support for the sacred-spark, reinforcement, and accumulative-advantage hypotheses.

Predocutorial performance and socialization. The calibre of the Ph.D. department

exhibited a significant independent effect on the chemists' productivity at the end of their first professional decade. Its impact is noteworthy, particularly because this variable did not significantly affect early productivity. The calibre of the Ph.D. department might reflect the enduring, albeit slight, impact of access of effective socialization on subsequent productivity. Institutions differ in the quality of instruction they provide, and these differences presumably affect their graduates' later performance. But department calibre may also have ascriptive effects on productivity (Crane, 1965; Hargens and Hagstrom, 1967) through its impact on the allocation of certain unmeasured resources to young scientists. For example, established scientists more often may invite young colleagues from prestigious Ph.D. departments to collaborate, either out of paternalistic feelings or from a desire to exploit the latter's familiarity with the newest techniques.

The importance of these "school" effects is highlighted by the absence of any independent effects of sponsorship. Collaborating with one's sponsor during graduate school led to increased early postdoctoral productivity, but any direct effect was lost by the end of the decade. Similarly, studying under a highly prolific sponsor increased recognition for early work, but had no direct effect on later productivity. This does not mean that the quality of sponsorship is unimportant for scientists' careers, but any measurable effects on productivity may be short-run and primarily ascriptive.

I argued that by providing additional socialization a postdoctoral fellowship should increase conformity to productivity norms and, hence, output; but, contrary to previous findings, the analyses revealed neither short- nor long-run effects. Apparently the effects of the precursors and consequences of a fellowship account for most of its zero-order association ($r = .17$) with decade productivity.

Organizational context. Beginning one's career in a university was a far more important determinant of decade productivity ($b^* = .29$) than one's graduate school credentials, and this effect was independent of university employment at

the end of the decade. Initial university employment could increase the decade productivity of scientists who subsequently left the university for several reasons, the most obvious being the continuation of collaborative work with former university colleagues. Former colleagues may also control the allocation of ongoing opportunities as conference organizers or journal editors, for example, or they may continue to serve unwittingly as a reference group. Some scientists who leave the university for less prestigious jobs may try to show former colleagues that they could have succeeded by university standards. Exposure to professional values regarding the primacy of research on one's first job may also facilitate their internalization (see, e.g., Cotgrove and Box, 1970: 127); chemists whose first jobs are in nonresearch-oriented contexts may view such values as purely academic. Finally, the enduring effect of early university employment may actually reflect universities' ability to recruit (if not always to retain) potentially productive chemists. While graduate students prefer university careers (Davis, 1962:158), in the face of growing economic pressures some of these more able scientists may be seduced by the financial prospects of industry. Controlling for predoctoral ability reduces the plausibility of this alternative, but does not exclude it.

Early productivity and the sacred-spark hypothesis. The data do not permit a direct test of the sacred-spark hypothesis. However, such a drive to publish should be fairly stable, leading to a strong partial association between early and later productivity. We see in equation (3a) that early productivity did not significantly affect decade output, but the absence of a direct effect does not necessarily disconfirm the hypothesis. While the failure to publish early in one's career may signal the absence of a spark, publication does not necessarily signal its presence, because a chemist's early publication rate may reflect the efforts of more experienced or motivated collaborators primarily responsible for joint efforts. If we assume that the order of authorship on articles reflects the authors' relative contributions, the partial association between

early first-authored articles and decade productivity provides a more realistic test of the sacred-spark hypothesis.

When both early productivity and the proportion of early first-authored publications were included in the regression, the latter did positively affect decade productivity (see equation [3b]). Apparently, early-publication rate, when measured to exclude publications for which the chemists may not have been primarily responsible, is associated with subsequent productivity. These results provide *very limited* support for the sacred-spark hypothesis: while their slopes are statistically significant, less than one percent of the variance in decade productivity among the sample as a whole can be attributed to the operation of a sacred spark.

While the sacred-spark hypothesis implies that strongly committed scientists will publish without social support, it does not necessarily follow that social mechanisms and social context have no effect on the productivity of individuals either blessed with or lacking a spark. Among chemists whose first jobs were in universities, early productivity significantly affected decade output. Since the emphasis on and rewards for productivity are generally greater in universities than in other sectors, a drive to publish should flourish in such settings. The significant-setting/early-productivity interaction is also consistent with the accumulative-advantage hypothesis. Universities allocate a variety of unmeasured rewards for early productivity (desirable teaching assignments, increased research facilities, etc.) that presumably foster continued productivity (Hagstrom, 1968). For nonuniversity chemists, other signs of successful performance (teaching evaluations, development of industrial applications, patents) bring similar organizational rewards, while publication is presumably incidental to career advancement.

Collegial recognition and the reinforcement hypothesis. Collegial recognition in the form of citations has a strong impact on decade productivity ($b^* = .308$). Since citation counts underestimate the number of citations for junior authors, I tried to assess the effect of this bias by

examining the relationships among the 98 chemists who had no junior-authored early publications. Among this subsample, the independent effect of early citations was 40% stronger than it was for the entire sample ($b^* = .456$ and $.308$, respectively; the equation for the subsample is not shown). Thus, of the variables considered here, early recognition is the most important determinant of decade productivity, accounting for almost 10% of its variance. However, this probably overestimates the effect of collegial recognition, which is certainly correlated with other, unmeasured structural rewards for early productivity that also facilitate productivity.¹⁹

Hagstrom's (1965:37) discussion of organizational incentives implies that the effect of recognition should vary by organizational context, with recognition from the scientific community being less important to scientists in contexts that do not emphasize research. To test this, I introduced into the regression equation a multiplicative term for first-job context and early citations. While significant, the effect of recognition on later productivity was *weaker* for chemists whose first jobs were in universities or other research-oriented organizations. Apparently in organizations that emphasize and immediately reward research and publication, formal recognition from the scientific community is less important in maintaining conformity to productivity norms than in nonresearch-oriented contexts in which rewards for productivity may be uncertain or scarce.²⁰

The impact of recognition on chemists' later productivity also varies with their

early productivity level. The greater one's early productivity, the weaker the effect of recognition on later output. Citations may be more reinforcing to late bloomers than to chemists whose early publication records are strong. The latter may have a strong drive to publish and need less social support to maintain their output or, perhaps, the intrinsic rewards of their early successes render productive researchers less vulnerable to the reactions of the scientific community.

Accumulative advantage. Without data on the chemists' research resources, I cannot directly test the accumulative-advantage hypothesis, which predicts both a direct reinforcement effect of citations and indirect effects from early productivity and early recognition mediated by the resources both can attract. Since research resources vary considerably by organizational context, a crude test of the hypothesis might use decade context as a proxy for resources. University employment at the end of the decade significantly increased decade productivity ($b^* = .280$), which is consistent with the accumulation of advantages. However, the selection hypothesis remains a viable alternative.

Chemists who began and ended their first decade in universities were significantly less productive than those who moved into universities from other contexts. While this result is consistent with a beneficial effect of mobility, it is as likely that universities require faculty they recruit from other contexts to be superior to their current faculty (see Cole and Cole, 1973:118).

SUMMARY AND CONCLUSIONS

Regression analyses of longitudinal data have provided estimates of the causal links between chemists' predoctoral training, early productivity, collegial recognition, organizational context, and productivity at the end of the first postdoctoral decade. After identifying methodological problems involved in using *SCI* citation counts to assess the effect of collegial recognition, I report tests of several hypotheses that have been proposed to account for variation in scientists' productivity.

¹⁹ The coefficient for citations will better estimate their true effects (in similarly specified equations) in fields where research work is less routine, since in routine fields such as chemistry (Hargens, 1975) the unmeasured resources that should accompany recognition are more likely to lead to increased productivity.

²⁰ A larger proportion of chemistry Ph.D.s work in nonacademic settings than in any other natural science, so nonacademic chemists may feel less isolated from colleagues doing basic research than similarly situated scientists in other disciplines. Insofar as this is true, the impact of formal recognition on nonacademic scientists' productivity should be even stronger in fields in which most practitioners are concentrated in university research.

Apart from the enduring effect of the calibre of the Ph.D. department, the effects of predoctoral socialization are slight and short run. Sponsor's productivity affects only early recognition; and predoctoral collaboration with one's sponsor increases early productivity, but does not affect decade productivity directly. Although sponsorship may ascribe to new Ph.D.s a professional status that affects their job placement and, indirectly, their productivity, educators apparently overestimate the direct effects of graduate training on scientific achievement.

The hypothesis that collegial recognition in the form of citations influences later productivity was supported, but to a smaller extent than past research on university scientists would suggest. This is not due to the heterogeneity of the sample: the effect of citations on decade productivity was *weaker* for those in contexts that emphasize research. In such contexts, immediate, informal recognition from research-oriented colleagues may be more important in maintaining productivity than the formal, but delayed recognition that citations provide. This is consistent with the greater direct effect of early productivity on decade productivity among university chemists than those employed in other contexts. Given the reward structure in most university departments, the act of publishing—signalling both successful professional performance and a variety of forthcoming rewards—may be especially reinforcing to university scientists. On the other hand, scientists in contexts that do not stress research and who thus lack informal or material rewards for publishing, may depend more on the formal response of the scientific community. Such recognition may symbolize their ties to the larger scientific enterprise and thereby encourage continued conformity to productivity norms.

The effect of organizational context points to the role of organization-specific reward structures and is consistent with the accumulation of advantages among scientists whose jobs provide access to resources that facilitate productivity. However, if context only affected performance in this way, its impact should dis-

appear when scientists change employment settings. The enduring effect of beginning one's career in a university may reflect on-the-first-job continuation of predoctoral socialization.

Although the analyses provide no direct evidence for the sacred-spark hypothesis, neither do they permit its disconfirmation. Chemists' predoctoral and early postdoctoral productivity had very small but significant independent effects on decade productivity. Moreover, the greater one's early productivity, the less the importance of recognition for later productivity; thus, highly motivated scientists—or those who quickly developed effective work habits—need less recognition to continue publishing. The expression "sacred spark" may be an unfortunate choice, since it suggests an innate drive uninfluenced by social factors. Any relatively stable propensity to publish probably depends on scientists' achievement needs, socialization and a constellation of competing interests and activities. The effect of such a latent propensity on actual performance would depend on a scientist's circumstances, including access to resources and rewards. The interaction effects on decade productivity of early productivity with both employment context and recognition should remind us that individuals' scientific drives operate in social contexts.

These results bear on the general question of maintaining normative conformity. Theories of normative conformity stress the importance of sanctions to maintain commitment induced by socialization (Goode, 1960: 254). While my results confirm the importance of *positive* reinforcement among professionals, they provide an incomplete picture of the role of sanctions in maintaining role performance. Anticipated or actual *negative* sanctions are also powerful motivators for scientists. Theories of scientific competition, for example, emphasize the consequences of fear of anticipation on research and publication (Collins, 1968; Gaston, 1971; Hagstrom, 1974). Thus, the extent and severity of competition in a scientific specialty may increase scientific productivity; and those factors that affect competition, such as specialty size, normative

consensus and functional integration (Hagstrom, 1974; Hargens, 1975), should, in turn, affect productivity indirectly. A single control for specialty, as used here, cannot capture such differences. Similarly, the publish-or-perish injunction expresses an important potential sanction for academic scientists. The actual motivating capacity of job insecurity should vary with conditions in the job market (which also vary by specialty). Finally, scientist may fear that past or present associates will view them as failures if their productivity declines (Fulton and Trow, 1974:54; Zuckerman, 1967: 402). If scientists publish in part to avoid losing face with significant others, poorly integrated scientists would have less to lose from low performance and, consequently, should exhibit lower productivity (see Homans, 1974, regarding the relationship between social status and conformity). Studies of scientists' actual and perceived positions in collegial networks are necessary to test these conjectures. I have shown that the same rewards vary in their importance with scientists' employment locations and exposure to formal reward structures. Surely integration into informal networks or invisible colleges is as important.

A COMPUTER SIMULATION OF THE EMERGENCE OF CONSENSUS IN CROWDS *

NORRIS R. JOHNSON
WILLIAM E. FEINBERG
University of Cincinnati

American Sociological Review 1977, Vol. 42 (June):505-521

A simple model of crowds seeking consensus for action is posited. Individual crowd members seek support from a sample of crowd members; successful ones attempt to influence the crowd toward a particular course of action. Consensus is achieved with a sufficiently reduced variability of opinions in the crowd. Independent variables are the initial distribution of opinions, crowd suggestibility and the average position of individuals seeking to influence the crowd. Outcomes of interest are whether consensus is achieved within a given time limit, the rapidity with which consensus is achieved, and the extremity of the consensus position reached. Most of the simulated crowds reach consensus within a given time limit; rapidity and extremity of consensus are considerably affected by interaction among the manipulated variables. A partial mathematical description of the model suggests that the results are nontrivial.

Many recent conceptualizations of crowd behavior emphasize the interaction within an initially heterogeneous collectivity which leads to the behavior characteristic of crowds. Although these recent approaches differ in emphasis, they share the view that crowd behavior occurs when a heterogeneous plurality of individuals, faced with an ambiguous or unstructured situation, reach a consensus for behavior through a process of interaction or milling. The basis for the consensus is variously explained by the theorists we discuss; however, all reject notions of contagion or convergence (see Turner, 1964a), which emphasize the distinctive aspects of crowd behavior, and focus in-

stead on its similarities with the action of more structured groups.

Our purpose in this paper is to draw from these recent discussions in order to synthesize some propositions about crowd processes, to describe a model of the internal dynamics of crowd processes based on these propositions, to specify more clearly the variables involved, and to test some implications through computer simulation.¹ Our synthesis initially will be limited to crowds rather than encompassing collective behavior in general.

Assuming that a heterogeneous collectivity is aggregated in a potential crowd situation and ignoring the basis for, and process of assembling (McPhail and Miller, 1973), there are at least three important questions that must be addressed in explaining the resultant concerted behavior. One must consider the effect of the initial distribution of individual characteristics, the function of influence or leadership on the individuals; and the change in behavioral intentions of the individuals as a reaction to the influence.

*A much different version of this paper, which emphasized the technical aspects of the computer simulation, was read at the Sixth Annual Pittsburgh Conference on Modeling and Simulation, School of Engineering, University of Pittsburgh, Pittsburgh, Pennsylvania, April 24-25, 1975. We wish to thank our colleagues, David C. Lundgren and Gregory J. Moschetti, for their perceptive and constructive suggestions. Our high suggestibility in relation to their comments, of course, makes them responsible for any inadequacies in this paper. We are also grateful to a colleague in the Mathematics Department, H. David Lipsich, who reviewed our mathematical calculations, and to anonymous reviewers who made valuable comments on an earlier version of this paper.

¹ We will not discuss the more macroscopic problems addressed by many theorists such as Smelser (1962) and recently advocated for study by Weller and Quarantelli (1973).

Individual Dispositions

Most sociologists reject explanations of collective behavior based on individual characteristics. Brown and Goldin (1973:173) argue that "neither the entrance of individuals into collective behavior nor their behavior during participation in collectivities can be explained by their underlying beliefs, attitudes, intentions, or states of motivation." Turner (1964a), in his elaboration of the emergent norm approach to collective behavior, McPhail (1971), in his analysis of research on civil disorders, and Weller and Quarantelli (1973), who are critical of both individualistic and interactionist approaches all concur. Research on crowd behavior is equally unsupportive of an individualistic interpretation. Studies of crowd members from the French Revolution (Rude, 1964) to recent student disorders (Foster and Long, 1970) find that participants in crowd behavior do not share distinctive psychological attributes.

Although no particular personality traits are characteristic of crowd participants, the *distribution* of individual characteristics, viewed as a property of an aggregate, is an important sociological variable to be considered in explanations of crowd behavior. In a crowd, the distribution of individual characteristics such as beliefs, motives, attitudes, behavioral dispositions or social statuses is frequently considered to affect either the probability of crowd behavior occurring or the form of the behavior that occurs. Smelser's (1962) "generalized belief" can be reduced to the beliefs of participants, as has been observed by Weller and Quarantelli (1973). Turner and Killian (1972:27) note the impact on the crowd of different types of individuals and suggest that consensus in an incipient crowd changes as the individuals who constitute the crowd change (Turner and Killian, 1957:138).

Berk (1972; 1974) and Johnson (1974) more explicitly discuss the effect of the distribution of individual dispositions on the crowd's behavior. Berk's (1974) observations of crowds suggest that the emergent action in the crowd is a function of what people bring to the scene as well as

the crowd situation. He contends that individuals in crowds bring a variety of motivations "ranging from passionate commitment . . . to simple curiosity" (Berk, 1972:312) out of which a consensus emerges through negotiation and compromise; if most crowd members are moderates, the modal action of the crowd will be moderate unless someone more militant persuades the moderates to act. Berk (1974:364) also notes that crowds in which there is little initial variation will reach consensus more readily. This suggests that if all were equally moderate, agreement could be readily reached on some moderate action; if all were militant, the rapid consensus would be on some militant activity. This implies an effect of the distribution of individual dispositions on both the time required for consensus and the consensus itself.

Johnson (1974) argues that the emergence of consensus in a crowd can be viewed as analogous with the "risky shift" which occurs in group decision making in the experimental laboratory. Concurring with Berk, he suggests that individual crowd members arrive on the scene willing to engage in a variety of different actions, from extreme to moderate. But where Turner and Killian refer only to a variety of motivations and Berk refers to moderates and militants, Johnson suggests that the variety of acts suggested or supported by different individuals might be arrayed on an extremity dimension similar to the degrees of risk in the risky shift experimentation. Through discussion, a shift to a position more extreme than the mean position of the individuals in the group is likely to occur.²

Thus, these three (Turner and Killian, 1972; Berk, 1974; Johnson, 1974) all argue that initially heterogeneous, incipient crowds reach consensus through an interaction process. Although none argues that persons involved in crowds have distinctive personality traits, each suggests that the *distribution* of behavioral intentions or dispositions in the aggregate affects the crowd activity—the probability

² A shift to a less extreme position is likely if the positions of the individuals are generally less extreme; thus, an incipient crowd might disperse and no crowd behavior emerge (see Johnson, 1974).

of crowd formation, the extremity of action, or the milling time required for consensus.

This argument, and the model developed subsequently in this paper, must assume that all members of the incipient crowd are oriented in the same direction, i.e., they all share a common focus. It is not applicable without modification to the possibility of a crowd which includes two sets of individuals with antagonistic objectives. For instance, a crowd involving militant blacks confronting white racists, e.g., a race riot, would have to be treated as two separate but interacting crowds. One could postulate that the dispositions among blacks ranged from passive opposition to the whites to a willingness to take violent action against them, and vice versa for the white racists. One would then examine the emergence of consensus within each group separately.³

Thus, following Johnson (1974), we believe that the individual dispositions in a crowd (whose members have a common focus) can be arrayed on some dimension of extremity or willingness to engage in non-normative actions. Persons might be willing, for instance, to engage in a peaceful march, but not in a sit-in. Others might be willing to engage in some violent demonstration. One can characterize a crowd on the basis of the shape of the curve which describes the initial distribution of individual participants.⁴ The curve might take any form, e.g., normal, U-shaped or skewed, depending on a variety of situational factors, but the form then has an independent effect on the crowd activity.

Influence on the Crowd

Unless one assumes that external factors are the sole determinants of crowd behavior or that each crowd member is

equally influential, one must assess the impact of influence or leadership on a crowd. Turner and Killian's (1972) emergent norm approach draws on Sherif and Harvey's (1952) experimental work with the auto-kinetic effect, which suggests that an emerging group standard will approximate the mean of the individual judgments, an expected outcome when all members are equally influential. With their *post hoc* notion of the "keynoter," however, Turner and Killian (1972:47) introduce differential influence into their interpretation. They suggest that, in ambiguous situations, the first forceful proposal of definite action will be followed. Although it might appear that a first forceful suggestion to disperse might be as readily followed as a suggestion to "storm the Bastille," Turner and Killian suggest that the speaker must receive support or he does not keynote the crowd. Thus, for a speaker to determine the course of crowd behavior, latent support for the position of the speaker must exist in the crowd. This implies an interaction effect of the speaker with the crowd's distribution of dispositions to behave.

Turner and Killian do not address the question of what types of suggestions are most likely to be *made*. If we assume a heterogeneous grouping with a variety of individual dispositions in the initial stages of crowd formation, it still appears that a first strong suggestion to "go home" might be as likely to be made as a suggestion to "storm the Bastille." Which suggestion was followed would then depend only on temporal primacy. Thus, the important and unanswered question here is whether the *occurrence* of a suggestion varies according to the extremity of the action involved. Given a wide range of individual dispositions, is a suggestion to go home as likely to occur as a suggestion to take some other, more extreme action?

Berk (1974) begins to resolve this issue with ideas from game theory. He argues that the ultimate crowd consensus is based on a rational calculation of potential rewards and costs to individuals. The perception of the possible payoff is a function of perceived support from crowd members and the potential rewards for action as opposed to inaction. Thus, Berk im-

³ A similar problem is mentioned by McPhail and Miller (1973:733) who discuss the possibility of some persons receiving instructions to assemble for "an anti-war demonstration, while others may be instructed to assemble at the same time and place to 'bug the peaceniks'" It is this kind of situation which requires the slight modification of our model.

⁴ We are not suggesting that the dispositions of crowd members can be arrayed on only one dimension. Willingness to engage in non-normative actions, however, seems to be an important dimension which could encompass a variety of motivations.

plies that all members of the crowd *seek* support, and those most likely to propose a course of action are the ones who perceive that their proposals will *receive* support. Where Turner and Killian see that support affects whether a speaker will be followed, Berk's reasoning leads to the suggestion that the perception of support affects whether an individual will *attempt* to influence the crowd. Since the individual in a crowd is not always able to judge accurately the crowd mood and calculate the probability of support, the crowd reaction to the speaker might or might not be supportive.

Although Berk addresses the question of who becomes a speaker, he does not ask who is most likely to seek support. If all seek support in a heterogeneous grouping in which all positions are represented, it seems likely that all are equally likely to find minimal support. Johnson (1974) addresses the latter issue by suggesting that persons at more extreme, or risky, positions are more likely to seek support than are more moderate individuals. He suggests that the correlation that exists between intensity and extremity of opinion (cf. Suchman, 1950) might account for the greater probability of the potential speaker coming from the extreme end of the distribution. More extreme persons, who hold their opinions more intensely, would be more concerned with influencing the course of action. A similar explanation for the shift to risk in experimental groups has been advanced by Burnstein (1971), who argues that persons supportive of risky positions are more confident, thus more assertive and influential.

Together these arguments support a position concerning the emergence of leadership that is more complex than Turner and Killian's notion of the keynoter, which implies that the first strong suggestion for action is followed by the crowd. It is congruent, however, with their observation that there may be a succession of potential keynoters who offer a variety of alternatives from which the crowd selects (Turner and Killian, 1972:89). This leads to a view of leadership as a function of both a group factor—the crowd distribution—and individual factors—the intensity with which individuals hold their

opinions. Following Johnson (1974), we believe that the extreme individual who holds his position intensely will take the first step toward influencing the crowd. That step is, according to Berk (1974), to sample the crowd in order to assess the degree of support for his position. If the individual perceives that sufficient crowd support does exist, he then attempts to influence the crowd by verbalizing his suggestion for action. Rather than uncritically following that suggestion, the crowd merely assesses it and reacts. The reaction involves the possibility of some shifting of individuals toward the speaker's position, which begins the process of consensus emergence. If consensus is achieved, the crowd is ready to act on the suggestion; if not, other individuals with other preferred courses of action seek support, make suggestions and get reactions from the crowd until consensus emerges or the crowd disperses.

Suggestibility

Whether it is labeled contagion (LeBon, 1960), social facilitation (Allport, 1924) or circular reaction (Blumer, 1939), nearly all students of collective behavior refer to a notion that individuals in the crowd situation are especially susceptible to the influence of others. The idea persists in the work of contemporary theorists, such as Turner and Killian (1972:32), who refer to the "heightened responsiveness of the individual to cues provided by others when situational anchorages are inadequate"; Lang and Lang (1961:221) and Smelser (1962:11) make similar arguments.

Even if the notion of heightened suggestibility is rejected (Couch, 1968), for consensus to arise in an initially heterogeneous grouping some individuals must change their opinions or behavioral intentions.⁵ Although consensus is generally not defined and is rarely thought of as unanimity (Berk, 1974), a shifting toward

⁵ This assumes that the individuals making up the group do not change. A group might also reach consensus through selective withdrawal and/or selective recruitment of individuals. The model developed in this paper assumes, however, that the group membership remains constant.

some basis for concerted action is typically thought to occur in crowds.

An important question is whether crowds vary in this tendency. Variation can be examined from two perspectives. One can look at individual differences in suggestibility, an early interest in communication research (Hovland et al., 1953) or situational variables that are conducive to suggestibility. The major emphasis by theorists of collective behavior is on the latter, which affects all members of crowds similarly. The situation which produces heightened suggestibility is variously referred to as ambiguous, problematical, unstructured or characterized by strain. Common to these terms and their definitions is some idea that collective behavior grows from situations for which the culture or social structure provides insufficient guidelines for behavior.⁶ The assumption is that social behavior occurs within a cultural and structural framework which provides definition for, and prescribed appropriate behavior in a variety of situations; however, not all situations are clearly defined. We will use the term "ambiguous situation" to refer to those situations which lack *sufficient* cultural definition for clearly determining appropriate behavior, and the term "suggestibility" to refer to a willingness to change particular dispositions in response to cues from others. Regardless of the particular terms used, the condition indicated by ambiguous situation is generally perceived as increasing "the suggestibility of individuals to the actions of others" (Turner and Killian, 1972:95).

⁶ Blumer (1939) says that collective behavior involves group activity "that comes into being and develops along lines that are not laid out by preestablished social definitions"; Turner (1964b:132) suggests that collective behavior occurs "when the conventional normative structure is internally conflicting or inapplicable to the situation at hand"; Shibutani (1966:172) refers to crises in which "the previously established social machinery breaks down"; Smelser (1962:47, 51-4) refers to structural strain as "inadequate functioning of the components of (social) action" and suggests that ambiguity is a principal kind of strain; Lang and Lang (1961:16-9) refer to "gaps" in the social structure; and Turner and Killian (1972:64) say that collective behavior occurs in situations where "cultural and social organization do not provide adequate directives for coping with the situation."

Although this suggestibility in crowds is contrasted with more deliberate behavior in structured groupings, the question of varying degrees of suggestibility in crowds is little discussed. If suggestibility is due to ambiguity, it seems that greater ambiguity would lead to greater suggestibility. This can be inferred from Turner and Killian's reliance on the experimental work of Sherif and Harvey (1952), which indicates a greater tendency for convergence on a group standard in more ambiguous situations. A similar inference can be drawn from the discussion of rumor by Allport and Postman (1947) and Shibutani (1966), both of which indicate that the magnitude of rumor spreading is a function of the ambiguity in the situation.

Given that incipient crowds may vary in suggestibility, whether the ultimate crowd action varies with suggestibility is unclear. It seems evident that the rapidity with which convergence on a group consensus occurs is a function of suggestibility, but its effect on *which* action of a range of possible actions emerges as the crowd consensus is less clear. Couch (1968) and Berk (1974), for instance, argue that crowd action is no less deliberate nor more emotional than other group decisions, implying that the suggestibility has no unusual effect on the outcome. Sherif and Harvey's (1952) work does not indicate that the group standard which emerges in more ambiguous situations differs from the standard emerging in situations of lesser ambiguity. Only the rapidity with which it emerges is affected. Shibutani's (1966) work, however, does indicate that rumors in situations of greater ambiguity are less congruent with general cultural standards, and Smelser (1962:72) adds that the generalized beliefs on which collective behavior is based are "short circuited," producing the "excessive" or "irresponsible" aspects of crowd behavior.

Thus, it might be argued that the heightened suggestibility in crowds varies with the degree of ambiguity in the situation, and the degree of suggestibility then affects the behavior that takes place in the crowd situation. It might affect either the rapidity with which convergence on some course of action occurs, or the course of

action itself. Since the idea of suggestibility assumes a "tendency to respond uncritically to suggestions" (Turner and Kilian, 1957:84), it must imply that individuals are shifting in the direction of some person or persons making a suggestion. If one could vary the degree of suggestibility of crowd members, by inference as a result of varying ambiguity in the situation, one might expect different outcomes from the crowd.

Summary

This discussion has identified three variables related to incipient crowds which might influence the outcome of crowd interaction, the dependent variables. These variables are operationally defined in our computer simulation model. We hypothesize that the distribution of individual dispositions in an incipient crowd, the type of influence efforts that are made and the suggestibility of the crowd (which we infer is due to the ambiguity of the situation) together determine the outcome of the interaction. Outcome variables include whether consensus for crowd action occurs, the rapidity with which it emerges and the form of the consensus—i.e., its location on a dimension of extremity.

Description of the Model

We begin by assuming that a large number (100 in our experiments) of individuals are gathered within some space without physical characteristics of consequence to the communication (and its informational content) and movement of the individuals. Individuals constituting the incipient crowd cannot leave the area nor can individuals enter the space after the process begins. Thus, there is a constant number of individuals with perfect communication among them. Ignoring why the individuals are gathered and the specific content of the issue which might incite the crowd into action, we assume that each individual has an initial disposition toward a particular course of action with respect to the issue, and all are oriented in the same direction as discussed earlier. The different courses of action are assumed to

fall along a discrete ten-point scale: position 1 is the least extreme course of action, and position 10 the most extreme.⁷ Finally, we assume that a finite amount of time is available for the individuals to agree on a course of collective action. Thus, there is the possibility that the individuals would not agree on a course of collective action within the time allowed.

The activity of the crowd in trying to reach consensus on some course of action is seen to involve three *recurring* processes: milling, influence attempts through speechmaking and crowd reaction (see Figure 1).

In the milling process, one *potential speaker* appears. This potential speaker, having a particular disposition to act, is chosen by matching a random number against a set of probabilities generated by a binomial distribution (see Appendix). Following Johnson's (1974) argument, the binomial distribution which generates the set of probabilities is set up to give greater likelihood of the chosen potential speaker having a more extreme disposition to act (i.e., six or more on the ten-point scale).

Each recurrence of the milling process, and thus the choice of a new potential speaker, is counted as the beginning of a new cycle in the model. The cycles represent time, and the crowd is restricted to an arbitrarily fixed number of cycles (50) within which it is possible to reach consensus on a course of collective action.

The milling process is one in which certain individuals survey the disposition of other crowd members, partly to discover whether there seems to be sufficient support for their own views. More specifically, the model has the potential speaker seeking support for his own disposition to action by sampling a small number (five) of crowd members and discovering the dispositions (on the ten-point scale) of the sample members. Because we have assumed that communication is perfect and

⁷ This ten-point scale follows Johnson's (1974) suggestion that the variety of dispositions in a crowd can be arrayed on an extremity dimension similar to the dimension of risk manipulated in the risky shift experimentation. The selection of ten as the number of possible dispositions is arbitrary, but it corresponds with the ten-point scale used in risky shift research.

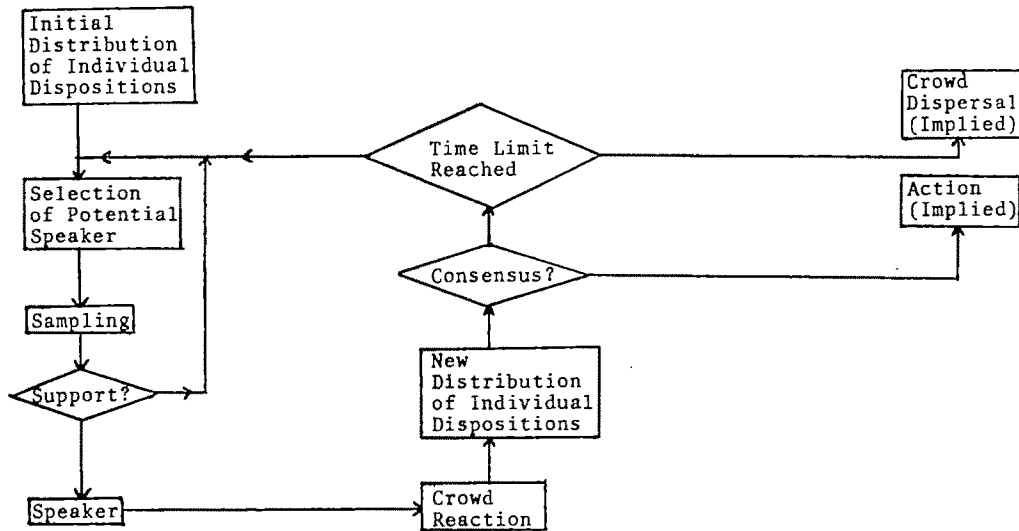

Figure 1. Schematic of Crowd Consensus Model

that physical movement is such that all crowd members are equally accessible, the sampling procedure means that all crowd members have an equal likelihood of being sampled.

The sampling is performed in the model by matching, for each sample member, a random number against a probability distribution obtained from the distribution of crowd members on the disposition scale. What is actually sampled are dispositions; as long as there are individuals having a particular disposition, there is a non-zero probability that that particular disposition will be included in the potential speaker's sample. In addition, sampling is with replacement.⁸ By sampling individual opinions, the potential speaker is testing whether his idea might be well received by the crowd as a whole.⁹

⁸ This raises the possibility that a sample will include a particular disposition more than once, even when that disposition is held by only one individual in the crowd; more so, the possibility exists in the model that the potential speaker, perhaps the only individual holding a particular disposition, might include that disposition (i.e., include himself) in his sample. For those who see this sampling with replacement as unrealistic or even absurd, we offer a rationale: first, the opinion of a particular crowd member might be accorded more weight than that of some other member; and second, a potential speaker might be sufficiently sure of his own position to accord it extra weight in deciding whether the sample is providing support for his position.

⁹ This is in accordance with Berk's (1974) notion that the appearance of support reduces the degree of

The model specifies three criteria for judging whether the sample provides sufficient support for the position of the potential speaker. Support is present if at least one criterion is fulfilled. They are: (1) at least one member of the sample has the same disposition as the potential speaker;¹⁰ (2) at least two members of the sample are not more than one scale position away from the potential speaker; (3) at least three in the sample are not more than two positions away from the disposition of the potential speaker. These criteria are somewhat arbitrary, but some support for these, or similar criteria, can be inferred from the small groups literature.

If the potential speaker's sample does not meet any one of the three criteria, a new potential speaker and new sample are chosen, and the number of cycles is increased by one, so long as the maximum number of cycles (the time limit) has not been reached. If the sample does meet one of the criteria for support of the potential speaker's position, the potential speaker becomes a *speaker*, and the second pro-

risk involved for the individual and increases the likelihood of a favorable outcome. This idea is similar to the diffusion of responsibility explanation of the risky shift. See Pruitt (1971) for a discussion.

¹⁰ Asch's (1951) experimentation indicates that the existence of one true partner permits one to act on his own beliefs and that increasing the size of the dissenting majority has little effect.

cess in a cycle is begun. Through means unspecified in the model, the speaker is able to make his views known to the other members of the crowd and seeks to influence others concerning the correctness or desirability of his position as a *collective* course of action. Because of our initial assumptions, the speaker can communicate his position equally well to all members of the crowd.

Members of the crowd then react individually to the speaker's message. Individuals whose positions are different from that of the speaker either maintain their position or shift their position toward the speaker's position on the ten-point scale. The model does not allow shifting away from the speaker's position.

We assume that the probability of shifting one position on the ten-point scale is constant, i.e., not dependent upon one's position on the scale or on individual suggestibility.¹¹ The number of positions shifted by an individual in response to the speaker's statement is found by use of the binomial distribution and the generation of random numbers. The maximum amount of shift by an individual is equal to the absolute difference between the individual and speaker positions, and the minimum shift is zero. Thus, the binomial distribution appropriate to finding the amount of an individual shift is determined by the maximum possible shift (which determines the number of binomial trials) and the constant probability of shifting one position.

¹¹ We are aware that certain attitude change theories would predict that subjects who hold more extreme positions are less likely to change their opinions in response to a communication. Social judgment theory (see, e.g., Sherif and Sherif, 1967) suggests that not only would a person in an extreme position be unlikely to change his opinion in the direction of a widely disparate suggestion, but might in fact shift *away* from the communication. For purposes of simplifying the model, because alternative explanations have been proposed for data relating extremity of opinion with resistance to change (see Keisler et al., 1969:238-301 for a critique of social judgment theory), and because even social judgment theory suggests that unstructured situations, as in crowds, widen the range of communication which can produce attitude change, we chose neither to permit the probability of shifting to vary with position on the scale of opinions, nor to permit shifting away from the speaker's position. These may be considered in a subsequent model.

The cumulative result of individual shifting in response to a speaker is a new frequency distribution of the crowd with respect to the ten-point scale of individual dispositions. We wish to know whether this new frequency distribution indicates that the individual crowd members have reached a degree of consensus concerning some course of collective action. If consensus has not yet been reached by the crowd, the model repeats the cycle of finding a potential speaker, potential speaker sampling, speechmaking and individual shifting, as long as the time (number of cycles) allowed for the overall process has not already been reached.

In the model we have arbitrarily stipulated two criteria, with at least one to be satisfied, for determining whether consensus has been achieved.¹² Both criteria involve the crude mode of the frequency distribution of individual dispositions. The first requires that the modal position on the ten-point scale contain at least 75 percent of the crowd members. The second is concerned with the amount of variability about the modal position. If at least 95 percent of the crowd is contained in the three scale positions (mode - 1, mode and mode + 1), this second criterion is met. With satisfaction of either criterion, the modal position is considered the consensus position reached by the crowd.¹³

Consensus for a course of collective action for the crowd is at least the reduction in variability of opinion about what is appropriate to the situation. This does not require total agreement among all members. While referring to consensus in crowds we recognize, as argued and demonstrated by Stark et al. (1974), that

¹² Consensus is rarely defined in a precise manner. Berk (1974:364n) says consensus "does not mean that everyone will engage in exactly the same actions. It means that a certain range of activities will be defined as acceptable and other activities defined as unacceptable." Our operational definition is consistent with this.

¹³ In those situations where the distributions of crowd member positions or opinions have more than one mode of equal frequency, consensus has not emerged even if the distribution otherwise satisfies the second criterion. Such situations (at least equally bimodal) indicate conflict and a lack of a clear-cut consensus and, therefore, require further "deliberation" by the crowd.

crowds involve "interactive, multiple and differentiated behaviors" (Stark et al., 1974:866). Berk and Aldrich (1972) also have clearly shown the heterogeneity of motives and behaviors present in the crowd. We suggest, however, that the range of behaviors has been narrowed through the process of interaction. In fact, if behavior is outside this narrowed range, it is not considered a part of crowd behavior. The criteria reflect this argument and, therefore, are not totally arbitrary. Each criterion operationally defines consensus as reduction in variability, the first in terms of the degree of modality and the second in terms of grouping of individual positions in the vicinity of the modal position.

Parameter Values

In the conduct of the experiment with our computer simulation model, we have allowed three parameters to vary from experiment to experiment: initial distribution of dispositions to action, the probability (PSPK) governing the set of binomial probabilities used to choose potential speakers, and the probability (PSHFT) governing the shifting of individual dispositions toward the speaker's position.

Five initial distributions were used: rectangular, U-shaped, "normal," skewed left and skewed right. Each distribution is a relative frequency distribution, based on the incipient crowd having 100 members. We required that no position in any of the distributions be initially empty (i.e., less than .01); thus the normal distribution is a slight modification of the binomial probability distribution for nine trials with $p = .5$. The U-shaped distribution is the normal distribution split in half and reversed. The two skewed distributions are reversals of each other; their basis was arbitrary. The rectangular distribution is self-explanatory.

The probability governing the choice of the potential speaker had one of four possible values: .6, .7, .8 and .9. The higher this probability, the higher the probability of the potential speaker coming from an extreme position.

The potential speaker who gained sufficient support from his sample of five indi-

viduals became a speaker, and the other individuals in the crowd react to his suggestion by shifting their positions. Individual shifting was governed by a binomial process in which the probability of shifting one position on the ten-point scale was invariant among the members of the crowd. This probability took values of .05, .10, .20 and .25. Increased shifting probability indicated an increased suggestibility for crowd members to the message of the speaker.

Thus, our experiment involved 80 sets of conditions of the model: five distributions \times four potential speaker probabilities \times four shifting probabilities. Within each set of conditions, 20 runs were performed. The 20 runs constitute a random sampling of results for the given parameters.

Finally, the maximum time allowed in each run for the crowd to reach consensus is 50 cycles. As indicated, a new cycle begins with the appearance of a new potential speaker. Given this time limit, some crowds would not reach consensus, while those that did would require varying numbers of potential speakers.

Results

Three independent variables related to incipient crowds were allowed to vary in the model as discussed above. Our results are presented in relation to the variation in initial distribution, value of PSPK, and value of PSHFT. No statistical tests are presented.¹⁴

Under each experimental condition, 20 independent runs of the simulation model were performed; therefore, a maximum of 20 crowds could achieve the stipulated conditions for consensus within the time limit of 50 cycles. Table 1 gives the results in which consensus is reached in the allotted time.

It appears that the least suggestible crowds (PSHFT = .05) were least likely to reach consensus within the allotted time, but the difficulty varied with the combination of initial distribution and extremity of potential speaker (PSPK). In general, as

¹⁴ We did perform some statistical tests which confirmed the significant interactions among the independent variables which seem apparent upon examination.

^a One cycle is equivalent to one potential speaker.

^b PSPK refers to the probability governing choice of the potential speaker. PSHFT refers to the probability of shifting one position on the ten-point scale.

the average potential speaker diverged from the majority of the crowd, it became more difficult for the crowd members to achieve consensus within the time limit. This interaction notion is strengthened by the decreasing number reaching consensus when the crowd is characterized by a skewed right distribution (66 percent of the crowd in positions 2, 3 and 4) and suggestibility is increased (PSHFT = .10). On the other hand, suggestibility when characterized by PSHFT greater than .05 (except with the skewed right distribution and PSHFT = .10) is always sufficient to overcome the inhibiting factors of initial distribution and average position of the potential speaker indicated by PSPK. That is, when the crowd is more suggestible, it will react more favorably to each speaker and thus be more likely to reach consensus and reach it more rapidly.

There are two ways in which we can measure the time required to reach consensus: the number of potential speakers and the number of speakers. Since the effects of the two are so similar, only data relating to the latter are reported. Table 2

shows the mean numbers of speakers for those runs in which consensus was reached. Holding initial distribution and PSPK constant (reading across), it is clear that increasing suggestibility, as measured by PSHFT, does decrease markedly the time necessary for consensus to be achieved in every case, although the amount of decrease varies among combinations of initial distribution and PSPK.

When we hold constant the initial distribution and shifting probability (reading down within blocks), the effect of increasing extremity of the average speaker (measured by PSPK) on rapidity of reaching a consensus is problematical. No single pattern is evident from column to column and from block to block. What seems apparent is that the effect of increasing PSPK on the mean number of speakers depends upon the initial distribution of the crowd. Leaving the exceptions unnoted, the effect of increasing PSPK in conjunction with either the normal or skewed right distributions is an increasing number of speakers; in conjunction with the U-shaped distribution, the result is a

	.8	21.67	9.55	8.00
	.9	20.90	10.80	7.90

decrease in mean number of speakers. The pattern in the relationship between PSPK and the number of speakers is U-shaped when the initial distribution is skewed left. With the initial distribution rectangular, no relationship between PSPK and number of speakers is evident.

In order to examine the effect of the initial distribution on time required to reach consensus when controlling PSPK and PSHFT, we ranked from lowest to highest the mean numbers of speakers under constant conditions and indicated these sets of rankings in Table 3. For example, from Table 2 we get the following values when PSPK = .6 and PSHFT = .25: 6.25 for the normal distribution (N); 9.65 for U; 8.20 for R; 6.90 for SL; and 7.10 for SR. Ranking these from lowest to highest, we get the following rank set designated A in Table 3: N, SL, SR, R, U. Under three sets of conditions, none of the twenty runs reached consensus; a rank of 5 was assigned to these non-consensus conditions.

Table 3 shows only four different sets of ranks characterizing the data, with two rank sets unique to particular conditions. While there is little difference between

rank set A and rank set D, the presence of sets B and C suggests an interaction among the conditions more complex than if only sets A and D appeared in their respective lines of the table.

Table 4 presents the mean consensus values of those runs reaching consensus under each of the experimental conditions. The modal position when consensus was achieved was regarded as the consen-

sus position, and the entries of Table 4 are the mean values of these positions.¹⁵

When initial distribution and suggestibility (PSHFT) are held constant, increasing values of PSPK yield a more extreme average consensus position. This seems intuitively obvious, since increasing values ultimately yield more extreme speakers to whose message the crowd is reacting by shifting their individual positions toward his position.

Suggestibility, as measured by PSHFT values, does not have any particular effect on the consensus reached, holding PSPK and initial distribution constant; however, if we consider only the differences between consensus means for PSHFT = .05 (or .10 when .05 yields no consensus runs) and for PSHFT = .25; i.e., between lowest and highest suggestibility, twelve differences are negative, six are positive and two differences are zero. This means that a crowd with low suggestibility is twice as likely as a crowd with high suggestibility, all else being equal; to arrive at a more extreme consensus position.

¹⁵ None of the model's crowds achieved consensus by fulfilling the first criterion of having at least 75 percent of the members of the modal position although, in a small number of runs, they came close.

For study of the effects of initial distribution on the consensus value reached, we employed a ranking procedure similar to that used in Table 3. These results are shown in Table 5. We were not able in this tabulation to assume anything about the ranks when no consensus was reached (unlike the procedure of Table 3), but we have made use of the similarities of rank sets.

We note two things about the information in Table 5. First is the great similarity between rank sets *a* and *b* (and therefore including *a'* and *b'*); and second is the considerable degree of consistency in rank sets among the varying conditions, since rank set *c* is also quite similar to *a* and *b* except for the absence of consensus runs with an initial skewed right distribution. Altogether, the results seem to indicate that the initial distributions, as portrayed by their means and standard deviations, exert a fairly consistent influence on the consensus position reached.

Some of our results may appear to be obvious consequences of the assumptions and variables included in the model. We certainly should have expected that the shifting probability indicating suggestibility would be inversely related to the rapid-

Table 5. Effect of Initial Distribution on Mean Consensus Reached

ity with which consensus is reached. The resultant direct relationship between average speaker position (indexed by the value of PSPK) and extremity of consensus reached also is not surprising and might be considered obvious from the definition of the model.

The effects of the independent variables in combination generally are not obvious. The results clearly point to interaction among the independent variables. A partial mathematical description of the model provides a means for testing some of the results. Specifically, if the mathematical results match results from the model, we would concede that the outcomes are strictly determined by the structure of the model and, therefore, somewhat trivial. On the other hand, a lack of correspondence between the mathematical results and those of the model would indi-

cate a more interesting situation and confirm the value of this approach.

The partial mathematical description¹⁶ involves two of the independent variables—initial distribution of dispositions in the crowd and the value of PSPK used in determining the positions of potential speakers. The value of PSPK, in conjunction with the binomial distribution, allows the calculation of the probabilities of potential speakers having each of the dispositions on the ten-point scale. Given the rules by which a potential speaker gains support for his position from a random sample of five members of the crowd, thereby becoming a speaker, and the initial distribution of dispositions in the crowd, it is possible to calculate, for potential speakers having each of the ten possible dispositions, the probabilities of gaining support and becoming speakers. The probabilities of potential speakers occurring with particular dispositions, varying with the value of PSPK, and the probabilities of potential speakers with particular dispositions gaining support, varying according to the initial distribution, can then be combined. This produces a set of probabilities, with each the probability of any potential speaker gaining support and becoming a speaker, for the specific PSPK and initial distribution conditions considered together. These probabilities are shown in Table 6.

The higher the probability value, the more likely that a potential speaker will gain support and become a speaker. In this mathematical formulation, we cannot

¹⁶ The procedure for the partial mathematical description and the distributions which constitute the basis for that description, are available from the authors on request.

Table 6. Probability of Any Potential Speaker Gaining Support from a Sample *

* From the partial mathematical descriptions; see footnote 16.

include the effects of the shifting probabilities; once a potential speaker becomes a speaker, the crowd members react to the speaker's message and the distribution of dispositions in the crowd changes, with our calculated probabilities then not strictly applicable to the new distribution of the crowd. It seems reasonable to expect, however, that crowds which are more likely *a priori* to provide support for potential speakers would, over the long run, reach consensus more rapidly than those crowds less likely to provide support. Therefore, we expect a strong direct relationship between the probabilities of Table 6 and the rapidity of reaching consensus (from Table 2), at least on some relative basis and controlling for the value of the shifting probability PSHFT.

Accordingly, we ranked the probabilities associated with the twenty conditions of Table 6 in descending order. Ranks also were assigned to the mean number of speakers under the same twenty conditions in each column of Table 2. This yielded four different rank orderings for the rapidity of reaching consensus under the PSPK-initial distribution conditions, controlling for the PSHFT value. The degree of relationship between the theoretical ranking (from Table 6) with each of the sets of ranks from Table 2 was then measured with Kendall's τ (τ). The rank-order correlations are all positive but are decidedly weak, ranging from $\tau = .258$ when PSHFT is .10 to $\tau = .383$ for a PSHFT of .05 (with a PSHFT of .20, $\tau = .338$ and $\tau = .318$ with a PSHFT of .25).

We conclude from these comparisons that the results of the model are not trivial outcomes of what was built in. This is not to suggest reification of the model, but that the model provides a useful starting point in a different approach to the study of a difficult phenomenon.

Discussion

We recognize the tentative nature of any conclusions about aggregates of real people in real situations; however if one accepts for the moment the assumptions of the simulation model, which were generally derived from theoretical statements

about real crowds, one can observe the interrelationships among the variables.

Although the distribution of individual dispositions in the aggregate has some effect on the outcome, one can argue from our simulation data that given the "right" conditions crowd behavior will emerge from any aggregate. The initial individual dispositions have no effect on whether consensus for action emerges under conditions of high suggestibility (Table 1). Inferring, as we have, that suggestibility is related to situational ambiguity, then we can argue that when the situation is sufficiently ambiguous, any aggregate, given sufficient milling time, will reach a consensus for crowd action. Under conditions of lower ambiguity, however, the distribution of individual dispositions does have an effect. Aggregates made up of individuals initially disposed toward some relatively extreme action (the skewed left distribution) will almost invariably take action under these conditions, but aggregates with other distributions (e.g., U-shaped and skewed right) rarely reach consensus under conditions of low suggestibility, assuming that leadership tends to be extreme.

A normally distributed grouping is also highly likely to take action regardless of the suggestibility involved. Many aggregates would constitute a normal distribution of those oriented in a particular direction. McPhail and Miller (1973) suggest that the prime determinant of whether individuals assemble at some location where collective behavior takes place is their access to communications about the event. Access to communications is based to some extent on an individual's predispositions; however, to the extent that communication is independent of such predispositions, a likely assemblage would be characterized by a normal distribution of dispositions to behave. These data indicate that this kind of aggregate could readily take on the characteristics of a crowd.

Whether an aggregate develops the consensus necessary for crowd action and the rapidity with which the consensus is developed are determined, according to the output from our model, primarily by the degree of suggestibility in the crowd.

Assuming again that suggestibility is a function of ambiguity, our results lend support to the notion that in highly ambiguous situations groups tend to reach consensus more rapidly than in less ambiguous situations. The degree of suggestibility, however, has little effect on the extremity of the consensus that emerges, a result that diverges from the notions of Shibutani (1966) concerning the content of rumor. The notion of suggestibility alone implies nothing about the content of the suggestion, although Turner and Killian (1972) and others argue that suggestions must be congruent with the "mood" of the crowd to be effective. Equating our distribution of individual dispositions with crowd "mood," evidence from Table 1 supports this notion when suggestibility is low. Under this condition, when the crowd mood is moderate (normal and skewed right distributions), the crowd is less likely to reach consensus when suggestions come from militant positions ($PSPK = .8, .9$) than when they come from less militant positions ($PSPK = .6, .7$).

Shibutani (1966) implies, however, that the content of rumor also is affected by suggestibility, i.e., content is less plausible and less congruent with general cultural norms under conditions of extreme ambiguity. If we assume that there is some relationship between his notion of plausibility and our notion of extremity, then our results are contradictory to Shibutani's idea. As indicated in the previous section, there is some evidence that consensus is less extreme under conditions of high suggestibility. Obviously this requires further research.

Modifications of the Model

We argued in the formulation of our model that suggestibility varies with the ambiguity of the situation and that individual differences in the willingness to accept normally unacceptable information could be ignored. We propose to examine whether individual differences in suggestibility within a crowd produce markedly different results from those presented here. This requires that individuals in the crowd be randomly assigned values for

PSHFT, the probability of shifting one position, with the means for the individuals equal to the respective constant values of PSHFT used in the present case.

This will aid us in formulating a more complex model, and we wish to present a bare outline of that model. An important aspect of the more complex model will be that physical space will be explicit, with the space (and distance) affecting communication and the physical movement of individuals. In our present model, the structures and processes through which individuals are influenced to change their preferred course of action are largely implicit. We believe, along with Berk (1974), that small groups are formed within the crowd for purposes of discussing the alternative possible actions and that consensus will emerge (a) if the groups achieve some consensus internally and (b) if the groups can reduce the variability between them. One means by which small groups can achieve consensus internally is by reduction of size; individuals who find their group's position incompatible with their own may move physically to find a more compatible group or leave the field of action altogether. Moreover, the group in which consensus is achieved may find it easier to change its position, as a group, when attempting to settle differences in position with other groups. This more complex model allows the occurrence of more than one potential speaker (and possible speaker) at a given time; this is not possible in the present model.

While the explicit inclusion of physical space and small group processes may not appear to portend a drastic change in the model, it does require that a considerable number of additional assumptions be made about connections among elements in the model. An arithmetic increase in the number of concepts to be dealt with creates a geometric, or even exponential increase in the number of assumptions and interconnections in the model. Making these assumptions and interconnections explicit is one of the great advantages of computer simulation, since this increases the chances of developing a coherent and viable theory.

Our reasons for discussing possible modifications of the present model have

been two-fold. The first is to emphasize that our present model is simple, the result of considerable abstraction from real situations. Second, we wish to indicate to those interested in such an approach one possible direction in which the approach might lead in the study of collective behavior.

APPENDIX

We start with N individuals distributed on a ten-point discrete scale ($D:d=1, 2, \dots, 10$) according to their dispositions to act, with 1 the least extreme and 10 the most extreme position.

Choosing the Potential Speaker

Using a parameter PSPK and the binomial distribution for nine trials, each position on the ten-point scale is assigned a probability of the potential speaker coming from that position d . The probability of the potential speaker having disposition d is

$$\Pr(D=d) = \binom{9}{d-1} (\text{PSPK})^{d-1} (1-\text{PSPK})^{9-(d-1)}$$

for all d . A cumulative distribution of the ordered probabilities is then found. This is all done once at the beginning of the run of the model. A random number R ($0 \leq R \leq 1$) is generated and matched against the cumulative probability distribution, with the position d^* of the potential speaker determined by where the random number falls on the cumulative distribution. If the position d^* is unoccupied by any of the N individuals, a search for a new potential speaker is begun by generating a different R .

Choosing the Potential Speaker's Sample

Given a potential speaker having disposition d^* , that potential speaker randomly samples (with replacement) n individuals from the total incipient crowd of N individuals. Since the N persons are classified according to dispositions d , the sampling is of dispositions.

The distribution of the N individuals (including the potential speaker) on the

ten-point scale is converted to a cumulated relative frequency distribution. A random number for each of the n sample members is then generated and matched against the cumulated distribution. Each of the n sample members is thus an individual disposition from the group of N individual dispositions.

Individual Shifting

Given that we have a speaker having disposition d^* , individuals in the crowd respond to the speaker's message by variably shifting their positions on the ten-point scale. The amount of shift for each individual is governed by a binomial distribution.

The probability of shifting one place on the ten-point scale is given by PSHFT and is constant for all N individuals. Since all shifting is assumed to be toward the speaker's position, the maximum number of scale places that might be shifted from position d to position d^* is $d - d^* = S$. For example, if the speaker is at position 8, an individual at position 3 can shift 0, 1, 2, 3, 4 or 5 positions, ending up at positions 3, 4, 5, 6, 7 or 8, respectively.

The probability of shifting s number of positions is then

$$\Pr(s) = \binom{S}{s} (\text{PSHFT})^s (1-\text{PSHFT})^{S-s}$$

For each value of S a different probability distribution is generated and cumulated. Each individual is assigned a random number each time a speaker appears; comparison between the random number and the appropriate cumulated probability distribution yields the appropriate amount of shift s and thus the individual's new position $d + s$.

SOCIAL EXCHANGE: PREDICTING TRANSACTIONAL OUTCOMES IN FIVE-EVENT, FOUR-PERSON SYSTEMS *

H. ANDREW MICHENER, EUGENE D. COHEN AND AAGE B. SØRENSEN

University of Wisconsin, Madison

American Sociological Review 1977, Vol. 42 (June):522-535

This paper reports an experimental test of Coleman's theory of social exchange. The theory utilizes information on interest (X) and initial control (C) to make predictions concerning the value of events (V), the resources of persons (R), and the pattern of control at equilibrium (C). The experimental paradigm, which incorporates three distinct five-event, four-person exchange systems, shows that the theory's predictions are highly accurate for V, R and C*. Competitive goodness-of-fit tests demonstrate that Coleman's theory surpasses alternative theories based on less input information. The findings substantiate previous tests of Coleman's theory conducted on smaller exchange systems.*

In an earlier paper, Michener, Cohen and Sørensen (1975) reported the first experimental test of Coleman's (1972) theory of social exchange. That test, while limited to small exchange systems involving four events and three persons, offered very encouraging results and showed that Coleman's theory was more accurate than several competing models.

Coleman's theory is intended to be highly general (i.e., to apply to any pure exchange system of m events and n persons). The theory's adequacy in this respect cannot be accepted on assumption, however, because social systems grow in complexity as they increase in size—a fact which makes the task of prediction more formidable. The present paper, therefore, reports a further experimental test of Coleman's theory, utilizing five-event, four-person exchange systems. Since these systems are virtually twice the scale and complexity

of those in the earlier test, data from the present study constitute evidence on the generality of Coleman's framework. Moreover, the data provide a basis for additional tests against alternative models.

Before reviewing Coleman's theory *per se*, it is useful to consider the general issues posed by exchange systems. In his classic statement on bilateral trade nearly a century ago, Edgeworth (1881) identified the key concepts for any exchange system and expressed the problem in formal terms. Any market system includes *persons*, who conduct transactions with one another, and it also includes *events*, which are commodities or services traded by the persons. Edgeworth noted that prior to the occurrence of any transactions, each person *controls* some portion of the tradeable events; additionally, each person has an *interest* in some or all of the events in the system.

To understand the issues posed by such a system, consider a concrete example. Assume there are four persons (i.e., Alex, Bernard, George and Dan) participating in an agricultural market consisting of five tradeable events (i.e., tomatoes, onions, plums, lemons and avocados). Assume that the system includes a total of 1,000 tomatoes, 300 onions, 200 plums, 800 lemons, and 400 avocados, and that control of these events is distributed as depicted in Table 1.

The control matrix (C matrix) in Table

* This study was supported by Grant 120365 from the Research Committee of the University of Wisconsin. Data analysis at the Madison Academic Computing Center was made possible through support, in part, from the National Science Foundation. The authors express their appreciation to Thomas Geissler and Allen Beck for assistance in data collection, and to James S. Coleman, G. William Walster and Martha R. Burt for valuable suggestions on the research procedures. Responsibility for any errors or deficiencies in this report rests, of course, with the authors.

Table 1. A Simple Agricultural Market

Interest Matrix (X)						Control Matrix (C)				
	tomatoes	onions	plums	lemons	avocados		Alex	Bernard	George	Dan
Alex	0	.3	.1	0	.6	tomatoes	.6	.2	0	.2
Bernard	.8	.1	.1	0	0	onions	.1	.7	.1	.1
George	.3	0	0	.4	.3	plums	.3	0	.4	.3
Dan	.3	0	0	.5	.2	lemons	.5	.5	0	0
						avocados	0	.6	.2	.2

1 indicates that, before any trades occur, Alex controls .6 (i.e., 600) of the tomatoes, .1 (30) of the onions, .3 (60) of the plums, .5 (400) of the lemons and none of the avocados. Bernard controls .2 (200) of the tomatoes, .7 (210) of the onions, none of the plums, .5 (400) of the lemons and .6 (240) of the avocados. George controls no tomatoes, .1 (30) onions, .4 (80) plums, no lemons, and .2 (80) avocados. Dan controls the rest. Note that control of any event sums to 1.0; thus, each person's control over an event represents that proportion of the commodity he owns (ranging from 0.0 to 1.0).

In addition to exercising control over the various events, persons also have interest in these events. The interest matrix (X matrix) in Table 1 details the extent to which each person has some interest in each of the four events. Interest is expressed in terms of the proportion of a person's total interest ranging from 0.0 to 1.0; that is, a given person's interest sums to 1.0 across all events. This conception of interest is analogous to a budget, in which a person allocates his purchasing power across various events in accordance with their importance to him. The more interest a person has in a given event, the more willing he is to commit his resources to obtain control over the event.

As shown in Table 1, Alex has no interest in obtaining tomatoes or lemons, but he does have a .3 interest in onions, a .1 interest in plums and a .6 interest in avocados. In other words, Alex has a large interest in avocados and a lesser interest in onions and plums. Bernard has a strong interest in tomatoes (.8) and a lesser interest in onions (.1) and plums (.1). George has approximately equal interest in tomatoes (.3), lemons (.4) and avocados (.3).

Dan has a prime interest in lemons (.5) and a minor interest in tomatoes (.3) and avocados (.2).

One might expect this situation to foster a series of trades, because the four persons don't have what they want and don't want what they have. The market system is in disequilibrium, and all persons can improve their positions by exchanging commodities with one another.

This simple example poses an important research question: *After all trades have occurred, who will control what?* That is, how much of the various events will be owned by each of the traders after all transactions? As emphasized by several writers (Edgeworth, 1881; Homans, 1961; Newman, 1965; Rapoport, 1970), this is the fundamental question to be answered by any exchange theory.

A second question posed by the example is: *What is the value of each of the events in the exchange system?* In other words, what is the relative "price" of each event? Since the traders have greater interest in some events than in others, one may ask which of the various commodities will command the highest price. Although of lesser importance than the issue of control after trading, this question has interested some theorists (Newman, 1965; Rapoport, 1970) and must be addressed by any general theory of exchange.

A third question is: *What is the relative power of each of the persons in the exchange system?* Since the traders begin by controlling different amounts of the various events and since these events differ in value, it follows that some traders will enjoy a more advantageous position than others. Various theorists (Thibaut and Kelley, 1959; Tannenbaum, 1962; Blau, 1964) have addressed the origins of power in so-

cial interaction, and it endures as an important issue.

In order to construct predictive models, theorists as far back as Edgeworth have found it useful to make restrictive assumptions regarding the exchange processes. One common assumption is that all persons in the system have full information about interests and control over events before trades occur. In the context of the agricultural example, this would mean that Alex, Bernard, George and Dan each know what the others want and what the others control. Another typical assumption is that all traders are guided by rational self-interest and seek to increase their gains through exchange; thus, persons will enter a trade only if it yields an increment in utility. A third assumption is that persons' interests are stable and not subject to change midway through trading. A fourth assumption is that events are divisible. In the previous example, the events meet this assumption; the event "tomato," for instance, can be divided to one part in 1,000 (since there are 1,000 tomatoes in the exchange system), while the event "onion" can be divided to one part in 300, etc.

While these assumptions are restrictive, they typify those made by many exchange theorists (e.g., Edgeworth, 1881; Newman, 1965; Rapoport, 1970; Coleman, 1972). Unfortunately, the stringency of these assumptions has hampered empirical assessment of exchange theory predictions, for virtually no markets found in natural settings meet all these conditions. Even relatively "pure" markets such as the commodity markets or the stock exchanges fail to satisfy the assumptions of full information and stability of interest.

It is possible, however, to *create* an experimental situation that meets the assumptions of exchange theory. In earlier work, Michener, Cohen and Sørensen (1975) established an experimental market paradigm involving four-event, three-person systems. The present research extends this paradigm to five-event, four-person systems. Systems of this size are substantially more complex than those used in the earlier research, and they afford a good basis for further tests of Coleman's theory.

The remainder of this paper first will describe the experimental procedures and report the findings. Next, it will detail Coleman's (1972) theory of social exchange and derive the relevant predictions. Finally, it will test goodness-of-fit to determine how well the theory's predictions match the empirical observations.

METHOD

Procedures

Subjects in the present study were 144 male undergraduates at the University of Wisconsin. For their participation, subjects received \$1.00 plus whatever money they could earn during the experiment. The subjects comprised 36 four-man groups, which were the units of analysis. Twelve groups were randomly assigned to each of three experimental treatments (termed Configuration 1, Configuration 2 and Configuration 3).

After arriving for the experiment, subjects entered a room containing a large square table. The four positions around the table were designated by name cards (Alpha, Beta, Gamma, Delta), and the experimenter randomly assigned subjects to these roles. During the experiment, subjects were free to talk with one another. Use of the Alpha, Beta, Gamma and Delta labels, rather than the subjects' own names, insured relatively impersonal and business-like interaction.

Seated around the table, subjects read an instruction sheet that described the basic situation. This explained that subjects would be trading colored chips, which constituted the exchangeable events in the system. These colored poker chips (red, white, blue, yellow and green) appeared on the table in full view of all subjects. In total, there were 500 chips, 100 of each color.

Before the trading began, each subject received another sheet of paper indicating the traders' interests and initial control over chips. Each person was staked to a given number of chips, which were piled directly in front of him on the table. The actual number of chips received by a sub-

ject depended both on the role he occupied (Alpha, Beta, Gamma or Delta) and on the experimental treatment (Configuration 1, 2 or 3) to which his group had been randomly assigned. The patterns of interest and initial control for the three experimental treatments are depicted in Table 2. For example, in those groups assigned to Configuration 2, person Alpha initially controlled .6 of the red chips, .1 of the white chips, .3 of the blue chips, .5 of the yellow chips and none of the green chips. In other words, Alpha had 60 red, 10 white, 30 blue, 50 yellow and 0 green chips. Beta had 20 red, 70 white, 0 blue, 50 yellow and 60 green chips. Gamma had 0 red, 10 white, 40 blue, 0 yellow and 20 green chips. Delta had 20 red, 10 white, 30 blue, 0 yellow and 20 green chips. Subjects understood that although some traders controlled more chips than others, they were to do their best with whatever they had.

Each subject received a sheet of instructions indicating how much interest the various traders had in each color chip. Interest was operationalized in terms of tenths of a

cent, so that subjects could earn money by accumulating colored chips in which they had some interest. For example, in Configuration 2, person Alpha had .6 interest in green chips and he therefore received .6¢ for each green chip he controlled at the end of all exchanges. Thus, if he controlled all 100 green chips when trading was completed, he would earn 60¢ from these alone. Similar payoffs could be earned for the other chips, depending on the degree of interest. This payment procedure meant that the last chip gained (of a given color) was worth as much monetarily as the first chip gained (i.e., no diminishing marginal payoff).

Note that the patterns of interest (X) and initial control (C) in Configuration 2 differ from those in Configuration 1 and Configuration 3. Configuration 2 depicts the same pattern as the earlier agricultural example with Alex, Bernard, George and Dan (compare Configuration 2 in Table 2 with Table 1). Configurations 1 and 3 are new. All three configurations were randomly sampled from a (hypothetically infinite) population of possible interest and

Table 2. Experimental Configurations 1, 2 and 3

	Interest Matrices (X)					Control Matrices (C)			
	Red	White	Blue	Yellow	Green	Alpha	Beta	Gamma	Delta
Configuration 1									
Alpha	0	.9	.1	0	0	Red	.6	0	.4
Beta	.3	.5	0	0	.2	White	.1	0	.1
Gamma	.3	0	0	.3	.4	Blue	0	.9	0
Delta	0	.8	0	.2	0	Yellow	0	.6	0
						Green	.4	0	.6
Configuration 2									
Alpha	0	.3	.1	0	.6	Red	.6	.2	.2
Beta	.8	.1	.1	0	0	White	.1	.7	.1
Gamma	.3	0	0	.4	.3	Blue	.3	0	.3
Delta	.3	0	0	.5	.2	Yellow	.5	.5	0
						Green	0	.6	.2
Configuration 3									
Alpha	.6	.2	.2	0	0	Red	.1	.9	0
Beta	.2	0	.4	0	.4	White	.1	.5	.3
Gamma	.9	0	.1	0	0	Blue	.8	0	.2
Delta	0	.2	0	.5	.3	Yellow	.4	.2	.2
						Green	.6	.1	0

control patterns for five-event, four-person systems. The only restriction applied to the sampling of configuration matrices involved rounding off entries in the matrices to the first decimal point. Thus, subjects exerted initial control in terms of tens (0, 10, 20, 30, . . . , 90, 100) and had interests expressed in terms of tenths (0, .1, .2, .3, . . . , .9, 1.0). Since Configurations 1, 2 and 3 differ among themselves, one would expect that the equilibrium pattern of control (after all trading) will be different for the configurations. This adds complexity, of course, but a *general* theory of social exchange must offer predictions for any possible configuration.

Having received information on interest and control for their configuration, the subjects began trading after the experimenter left the room. The experimenter was blind to all theoretical predictions, and his absence from the room precluded experimenter bias.

Subjects were free to negotiate any trades they wished. The only stipulation was that all deals were to be two-way (i.e., between two traders); no three-way or four-way deals were permitted, although subjects could achieve complex deals by a series of two-way trades. The various groups (which could be monitored over an intercom system) differed greatly in the way they conducted exchanges. Some were amicable and jocular; others were tough and sarcastic. Some made only a few trades (involving large numbers of chips); others racked up more than 25 exchanges (involving only a few chips each time). The order and sequencing of trades differed from group to group and appeared to follow no standard pattern. In several cases, a subject decided to conduct an auction for his chips; in other groups, subjects utilized complex mathematical calculations to determine what they considered a proper rate of exchange. When a transaction occurred, subjects literally exchanged chips. Thus, hundreds of chips changed hands during the experimental session. Equilibrium was reached when all subjects decided that they no longer wanted to trade or found that they couldn't promote any further trades with the other subjects. At

that point, they informed the experimenter via the intercom. He reentered the room, carefully tallied who possessed which chips, and administered a postexperimental questionnaire to assess the subjects' perceptions of the trading.

Fixed Parameters

As indicated above, exchange theories in general (and Coleman's theory in particular) are predicated on a set of explicit assumptions. At the operational level, these assumptions must be treated as fixed parameters. Care was taken in the present study to set fixed parameters in accord with theoretical assumptions.

Self-interest motivational orientation. Perhaps the most critical (and limiting) assumption of exchange theory is that each trader pursues his own self-interest. This involves neither a moral assertion nor a presumption of plutocracy; rather, as Newman (1965) has emphasized, it is merely an assumption that traders use certain decision rules in deciding when to favor one potential trade over another. Meeker (1971) places self-interest in perspective by noting that persons can adopt any of several motivational orientations in face-to-face interaction. In addition to self-interest, these include altruism, competition, group gain, equity, status congruity, reciprocity, etc. Consistent with the assumptions of Coleman's theory (1972; 1973: ch. 3), the present study instilled a self-interest motivational set and discouraged the adoption of other orientations. Written instructions urged a self-interested orientation by including such directives as "get the largest number of chips," "obtain the biggest profit," and "do as well as you can." Since most persons will not automatically adopt a purely self-interested stance in face-to-face interaction, steps were taken to legitimate this orientation. First, subjects were informed they had been randomly assigned to roles (Alpha, Beta, Gamma, Delta); this eliminated status congruence as a criterion for trading. Further, each subject realized that the others were adopting a self-interested orientation, and this legitimated his own self-interested stance and undermined any collective or group-gain orientation.

Moreover, the instructions explicitly indicated that traders should not consider themselves in competition with one another; for example, Alpha's success as a trader should be assessed only in terms of his outcomes relative to those of the Alphas in other groups, not relative to those of Beta, Gamma and Delta in his own group. Finally, a pure equity orientation was minimized because the instructions defined "fairness" as "doing as well as you can for yourself." Expressed another way, the instructions espoused a norm of rational self-interest and outlawed other orientations commonly seen in face-to-face interaction.

Subjects' responses to two questions on the postexperimental questionnaire indicate that these instructions accomplished their purpose. One question asked: "How motivated were you to obtain as many valuable chips for yourself as possible?" The other asked: "To what extent were you trying to get the largest profit possible for yourself?" The mean responses on nine-point scales to these two questions were, respectively, $\bar{X}=7.29$ and $\bar{X}=7.57$, which indicate a very high level of self-interested orientation, especially for a face-to-face situation.

Full information. Most exchange theories (including Coleman's) assume that all participants have full information regarding control and interest. This was fixed as a parameter in the present study, and all subjects operated with complete information. Since the colored chips were stacked in front of the subjects on the table and actually changed hands whenever a transaction occurred, all subjects knew who controlled what at all times. Moreover, subjects had a sheet of paper detailing the interest matrix for their particular configuration. This specified each person's interest in each event, assuring that everyone's interests remained stable throughout the trading. A fixed pattern of interest obviates the use of certain power tactics (i.e., withdrawal and demand creation, as detailed in Michener and Suchner, 1972), which would otherwise affect the pattern of trades.

Divisibility of events. The present frame-

work included five events (red, white, blue, yellow and green chips), each of which was divisible to one part to 100. This high degree of divisibility enabled the subjects to operate with substantial precision in establishing exchange rates among the five events.

Outcome Measures

This study incorporates three dependent variables; these parallel the three research questions raised in the introduction. Items on the postexperimental questionnaire measured subjects' perceptions of each trader's resources and each event's value. These measures will be symbolized R_o (for "observed resources") and V_o (for "observed value"). The third dependent variable, the pattern of control over events *after* trading (symbolized C^* , for "observed control at equilibrium"), was determined via direct observation of the chips.

To measure resources, subjects rated each person (including themselves) in terms of four semantic differential scales. These scales were *strong-weak*, *powerful-powerless*, *potent-nonpotent* and *dominant-submissive*. Data from previous research (Michener and Cohen, 1973; Michener, Lawler and Bacharach, 1973) indicate that these scales measure resource position (as opposed to measuring other aspects of power such as aggressiveness or resistance). In the present study, a score was obtained for each person by summing the four items as rated by all four subjects, cubing the sum to sharpen the differences among persons, and then dividing that number by the total score for all persons. This procedure generates a vector of coefficients (R_o) for the persons in the exchange system; these coefficients sum to 1.0. As in past research, these scores prove highly reliable, with a median Cronbach's alpha of .918 (computed across four perceivers for each of four persons perceived).

The value of events (as perceived by subjects) was measured on the postexperimental questionnaire by four semantic differential items: *valuable-worthless*, *important-unimportant*, *sought after-not sought after*, *desirable-undesirable*. Instructions directed each subject to rate each color

chip in terms of its value and importance to all traders within the system and not just to himself. A value score was obtained for each event by summing the four items as rated by all four subjects, cubing the sum to heighten the differences among events, and dividing that total number by the total score for all events. This procedure generates a vector of coefficients (V_o) for the events in the exchange system; the elements in the vector sum to 1.0. These scores prove highly reliable, with a median Cronbach's alpha of .887 (computed across four perceivers for each of five events).

The third dependent variable is C^* , control over events after trading. (Note that the C^* matrix differs from the C matrix, which is the pattern of control before trading.) Since the colored chips changed hands during the trading, the experimenter could simply tally who had what chips when trading was completed. He did this in full view of all subjects and then double-checked for accuracy by reading aloud the amounts he had recorded. Because the subjects were paid according to this count, this procedure provided a measure of C^* that was virtually error-free. Entries in the C^* matrix were computed from the raw data by dividing by 100 the number of chips of each kind held by each subject. Thus, final control of a given event summed to 1.0 over all persons.

DESCRIPTIVE RESULTS

Measures of the three dependent variables (R_o , V_o , C^*) were obtained for each of the 36 four-man groups in the study. From these raw data, mean values for each of the three configurations were computed (12 groups per configuration). Table 3 presents the results (R_o , V_o , C^*) for Configurations 1, 2 and 3.

As might be expected, the results for any given configuration differ from those for the other configurations. The sheer complexity of the empirical data highlights the need for a theory to interpret the findings. The important task, of course, is to predict R_o , V_o and C^* not just for one configuration, but for all three. Coleman's

theory, as will be seen below, is sufficiently general to do this.

COLEMAN'S THEORY OF SOCIAL EXCHANGE

Coleman's (1972; 1973: ch. 3) theory pertains to any exchange system of m events and n persons, where persons have a fixed structure of interest in events (X) and an explicit pattern of initial control over events (C). The theory is based on the same assumptions introduced at the beginning of this paper and established as fixed parameters in the experimental setting. These assumptions include: (1) persons will strive to achieve their self-interest; (2) events are divisible; (3) all persons possess full information concerning the C and X structures.

In Coleman's symbolism, the amount of initial control over event i by person j is represented by c_{ij} , where $0 \leq c_{ij} \leq 1$ and $\sum_j c_{ij} = 1$. Since events are divisible, c_{ij} represents the fraction of i over which person j has full control.

The amount of interest that person j has in event i is represented by x_{ji} , where $0 \leq x_{ji} \leq 1$ and $\sum_i x_{ji} = 1$. That is, x_{ji} represents the fraction of his resources that person j allocates (during trading) toward control over event i , independent of the total size of his resources and independent of the value of event i in the system.

Coleman's theory defines resources for each person in the exchange system as follows:

$$r_j = \sum_{i=1}^m v_i c_{ij} \quad (1)$$

where r_j is the resources held by person j , v_i is the value of event i in the system, and c_{ij} is the initial control that person j has over event i . Expressed in words, equation (1) says that the resources held by person j consist of the sum of initial control he has over all events, each event weighted by its value. Clearly, a person will hold a lot of resources if he has substantial control over a lot of events, provided these events are valuable in the system.

Coleman's theory defines the value of each event as:

$$v_i = \sum_{j=1}^n r_j x_{ji} \quad (2)$$

where v_i is the value of event i in the system, r_j is the resources held by person j , and x_{ji} is the interest of person j in event i . Equation (2) says that the value of an event is the sum of interests in the event, each person's interest weighted by his total resources. This means that an event will be very valuable if many persons have a substantial interest in the event, provided they hold a lot of resources.

Note that resources is defined in terms of value (equation [1]) and that value is defined in terms of resources (equation [2]). At first this may appear circular, but it is possible to achieve a simultaneous solution for these equations by using the fact that the total quantity of resources in the system sums to one (i.e., $\sum_j r_j = 1$) and the value of all events sums to one (i.e., $\sum_i v_i = 1$).

The prime objective of exchange theory is to specify who will control what after trading has been completed—in other words, to predict C^* . Coleman's theory uses c^*_{ij} to symbolize the amount of control over event i that person j has at equilibrium (after trading), and it stipulates the equilibrium condition as:

$$v_i c^*_{ij} = r_j x_{ji}. \quad (3)$$

This equation says the exchange system will attain equilibrium when the amount of resources a person commits to control an event ($r_j x_{ji}$) equals the value of full control over the event times the proportion of control he actually achieves ($v_i c^*_{ij}$). If this condition does not hold for all persons and all events, then at least two persons can benefit from further trading, and further exchange is predicted to occur until the equilibrium condition is reached.

Given information on C and X and equations (1), (2) and (3) above, it is possible to derive predictions regarding R , V and C^* for the three configurations used in the experimental situation. Coleman's pre-

dictions for the outcomes of Configurations 1, 2 and 3 appear in Table 4.

GOODNESS-OF-FIT

How well does Coleman's theory predict the empirically observed outcomes (R_o , V_o and C^*_o) for the three configurations?

It is useful, first, to compare visually the empirical outcomes (Table 3) against the predicted outcomes (Table 4). Note the substantial correspondence between observations and predictions for resources (R) and for value (V). With the exception of one reversal for resources in Configuration 3 and two reversals for value in Configuration 2, Coleman's predictions closely match the data. Even more impressive is the correspondence between empirical observations and the predictions for C^* . The match between observed and predicted coefficients is very close, with the only important reversals being the red chips in Configuration 1 and, possibly, the red chips in Configuration 3. This correspondence appears all the more striking when one remembers that Coleman's theory is making predictions for three different five-event, four-person systems.

Goodness-of-fit for C^*

To obtain a more precise assessment of the theory's predictive capabilities, a test was performed for goodness-of-fit. First, a discrepancy index, d , was defined as the square root of the sum of the squared differences between observed and predicted values, i.e.,

$$d = \sqrt{\sum_{i=1}^m \sum_{j=1}^{n-1} (c^*_{ij_o} - c^*_{ij_p})^2} \quad (4)$$

where $c^*_{ij_o}$ is observed control (after trading) over event i by person j and $c^*_{ij_p}$ is predicted control over event i by person j .¹ This index reflects the discrepancy be-

¹ Computation of the discrepancy index involved summation over m events but over only $n-1$ persons. Since the rows in the C^* matrix are constrained to sum to 1.000, the degrees of freedom in this matrix are limited to $(m)(n-1) = (5)(4-1) = 15$.

tween data and theory; perfect correspondence between observed and predicted outcomes will yield an index score of zero, while poor correspondence will yield a large positive score.

Using Coleman's predictions, discrepancy scores were computed for each of the 36 groups in the experiment. Table 5 presents the mean discrepancy scores for C^* in Configurations 1, 2 and 3. A comparison across configurations reveals that none of the means are equal to zero, indicating some difference between observations and predictions.

An obvious question is: Does Coleman's theory predict the data better than simpler alternative models? This is an important issue because Coleman's theory poses large initial-information requirements; that is, it requires knowledge of both the C and X matrices to make predictions regarding C^* . In many naturally occurring exchange situations, either the C matrix or the X matrix (or both) is unknown or only partially known. If an alternative model requiring less information proves as efficient as Coleman's in predicting outcomes, that model would be preferred.

Three alternative models with low information requirements will be considered here. The first is an elementary baseline model that needs only initial information on m (the number of events) and n (the number of persons). This model predicts that each person will control an equal proportion of each event after trading (that is, $c^*_{ij}=1/n$). Although extremely simple, it can be interpreted in substantive terms as an equalitarian model in which traders are predicted to share all outcomes equally.

A second alternative requires information regarding the initial C matrix as input. It predicts simply that $c^*_{ij}=c_{ij}$. In other words, in the absence of information on X ,

this model takes initial control (C) as the best approximation of final control (C^*).

A third alternative model requires only information concerning interest (X). This elementary model predicts that final control (C^*) is a function solely of interest in events. That is, it predicts that traders will achieve control over an event in proportion to their interest in that event; expressed formally,

$$c^*_{ij}=x_{ji}/\sum_j x_{ji}.$$

To ascertain the predictive adequacy of these three alternative models, discrepancy scores (equation [4]) were computed for each model on the 36 groups in the study. The mean discrepancy scores for these models (i.e., equalitarian, C -only, proportionate interest) are presented in Table 5.

To test Coleman's theory against the three alternatives, the discrepancy scores were analyzed in a 3 (configurations) \times 4 (theories) split-plot factorial analysis of variance (cf. Kirk, 1968:248-83). Each group was nested within one of the three levels of the configuration factor (i.e., 12 groups per configuration). The repeated measures factor (theory) was crossed with configuration.

Results indicate that the difference between theories is statistically significant, $F(1,33)=555.44$, $p<.01$. There is no significant main effect of configuration, $F(2,33)=3.17$, $n.s.$, but the data show a significant configuration \times theory interaction, $F(2,33)=15.27$, $p<.01$, on the discrepancy scores.²

* Because this analysis involved repeated measures over four theories for each of the 36 groups, the Geisser-Greenhouse correction for dependency of observations has been applied to all F -tests reported here. This correction is extremely conservative. Computational procedures are identical to those of a conventional test except that

Table 5. Mean Discrepancy Scores for Final Control (C^*)

Theory	Configuration			Mean across Configurations
	1	2	3	
Coleman	.8523	.6992	.6299	.7272
Equalitarian	1.5049	1.4704	1.5154	1.4969
C -only	2.2701	2.1075	2.1757	2.1844
Proportionate Interest	.8124	.8560	1.3820	1.0168

This interaction results primarily from the differential performance of the proportionate interest model (i.e., poorer performance in Configuration 3).

Separate planned comparisons show that, across the three configurations, Coleman's theory fits the data better than the equalitarian model, $t(33)=20.15$, $p<.01$, better than the C-only model, $t(33)=38.15$, $p<.01$, and better than the proportionate interest model, $t(33)=7.58$, $p<.01$. (The critical values of all tests reported here have been adjusted conservatively to maintain an experimentwise error rate of .01.) These tests show that Coleman's theory is superior to several alternative models having lower information requirements. While Coleman's theory needs more initial information to make predictions regarding C*, its predictions are more accurate than those of the simpler models. This conclusion reinforces that of the earlier experimental test on smaller exchange systems (Michener, Cohen and Sørensen, 1975).

Goodness-of-Fit for V and R

Beyond question, the most important test of Coleman's theory is that involving C*, the prime dependent variable. However, it is possible to conduct ancillary tests of Coleman's theory using the data on value (V) and resources (R). The empirical results (V_o and R_o in Table 3) are based on measures known to be highly reliable and (in the case of the measure for R) to have the intended discriminant validity. These results are closely matched by Coleman's predictions (V_p and R_p in Table 4). With few exceptions, Coleman's theory predicts the rank-ordering of resources and value in all three configura-

tions. A comparison of Tables 3 and 4 reveals only one reversal for resources (Configuration 3) and two reversals for value (both in Configuration 2). Moreover, as shown in Table 6, the mean discrepancy

scores for value, $d = \sqrt{\frac{m-1}{\sum_i (v_{io} - v_{ip})^2}}$, and

for resources, $d = \sqrt{\frac{n-1}{\sum_j (r_{jo} - r_{jp})^2}}$, assume

relatively small magnitudes, indicating a close fit between the empirical results and Coleman's predictions.

As a test of Coleman's predictions for value and resources, discrepancy scores were computed from the data for several alternative models based on less input information (m and n only, C only, X only). Results of comparative tests show that Coleman's predictions are superior in all cases for resources ($p<.01$) and for value ($p<.02$).³

DISCUSSION

The present test, in conjunction with the research on smaller exchange systems reported in Michener, Cohen and Sørensen (1975), provides some empirical support for Coleman's theory. The theory performs nicely in predicting outcomes for the five-event, four-person systems treated here. Presumably, the theory would apply to even larger systems, although the present

³ The sole exception to this statement is an alternative model that treats value as proportional to total interest: $v_i = \sum_j x_{ij} / n$. A test shows that the mean discrepancy score (across configurations) based on predictions from this model does not differ significantly from that based on predictions from Coleman's model, $t(33)=1.26$, *n.s.*

the degrees of freedom are reduced. For a detailed discussion of the Geisser-Greenhouse correction, see Kirk, 1968:142-3.

Table 6. Mean Discrepancy Scores for Value (V) and Resources (R)

Variable	Configuration			Mean across Configurations
	1	2	3	
Value (Coleman)	.1304	.2046	.1503	.1617
Resources (Coleman)	.1882	.1218	.1954	.1685

data do not isolate the limits of applicability.

Beyond the question of size, one must note that Coleman's theory is predicated on several strong assumptions. The present study purposely incorporated these assumptions as fixed parameters, but it remains for future research to determine whether the theory will predict adequately if these parameters are relaxed.

Several assumptions deserve special attention. First, one may ask what happens to the theory's predictive power when traders operate without complete information regarding control (C) and interest (X). Situations of imperfect information give rise to inefficiency; they also provide an opportunity for certain power tactics, such as feigned withdrawal and extension of the power network (Michener and Suchner, 1972). Coleman's theory certainly will be less applicable when traders have only partial information, but the important issue is *how much* less applicable. By experimentally varying the degree of information held by traders, future research could determine the theory's sensitivity to this parameter.

Second, Coleman's theory assumes that persons act in their own self-interest. Empirical researchers recognize that while persons are capable of adopting a self-interested orientation, they can also adopt other motivational sets such as altruism, equity, status congruence, competition, etc. Informal experimentation by the present writers suggests that Coleman's theory is sensitive to relaxation of this parameter and that it loses some of its predictive capacity when subjects adopt other orientations (such as equity). The important question, of course, is *how much* predictive power is lost when traders adopt other motivational sets?

Third, Coleman's treatment of control implies that when a person trades an event, ownership is completely forfeited to another person. This is a reasonable assumption for material goods, but it does not apply readily to other commodities such as information. As Rosen (1966) has observed, a person can trade (or give) in-

formation to another while continuing to "control" it himself. Do the predictions from Coleman's theory apply to commodities having this property or is a distinct theory required?

While issues such as these remain open for future study, the conclusion from the present research is that Coleman's theory performs better than simple alternative models under the given fixed parameters. The theory is an important element in the study of interpersonal exchange, and future experimentation on exchange systems should adopt it as a starting point.

The Rise and Fall of the Cyprus Republic

Kyriacos C. Markides

Much has been written on the international politics affecting the island of Cyprus, but this is the first serious study of the internal dynamics of the Greek community that made foreign intervention in 1974 possible and successful. Markides shows why the internal contradictions of the Cypriot social and political system and the popular reliance on the charismatic leadership of Archbishop Makarios prevented the growth of viable governmental and political structures that could have offered effective resistance.

"A historical, sociological analysis of the major community in a country which, though smaller in area than Connecticut and containing only slightly over half a million people, tragically occupies a crucial position in the geography and power politics of the Eastern Mediterranean."—Leonard Doob \$12.50

ITEMS (Continued)

Illinois University, Carbondale. The present paper completes his study of the American family in historic perspective. His most recent publication is *Marital Incompatibility and Social Change in Early America* (Sage Research Papers, Vol. 4, 1976). He is currently reexamining black family organization and structure under slavery, including fertility and sexuality. MARTIN SCHULTZ is a Ph.D. candidate in Sociology at the University of Southern Illinois, Carbondale. His research interests are the family and the methodological problems of reconstructing family history. He is presently reconstructing American divorce rates and patterns prior to the collection and publication of federal divorce statistics. MARY O'HARA is a graduate student in the Department of Sociology, University of Southern Illinois, Carbondale. Her major interest is the sociology of the family and the community. She is the coauthor, with Herman Lantz, of a forthcoming paper on the Jewish family in early America.

■ REEVE VANNEMAN (American Perception of Class and Status) is Assistant Professor of Sociology at the University of Illinois, Urbana. His current research includes work on class divisions in the occupational structure and the role of the bureaucracy in Asian stratification. FRED C. PAMPEL will be Assistant Professor of Sociology at the University of Iowa in the coming year. He is presently completing his doctoral dissertation, *Social Indicator Models of Changes in the Status of the Aged*, at the University of Illinois, Urbana.

■ CHARLES C. RAGIN (Social Bases of Political Regionalism) is Assistant Professor of Sociology at Indiana University, Bloomington. His interests include political sociology, social change and social theory. His current research is on quantitative historical analysis of the social bases of political regionalism in Western democracies and cross-national research on dependency and development. He is also studying continuities in sociological theory.

■ CHRISTOPHER J. HEWITT (Democracy and Equality in Industrial Societies) is Assistant Professor of Sociology at the University of Maryland, Baltimore County. He is currently studying conflict between "communal" groups, divided by race, religion or language.

■ IVAN LIGHT (The Ethnic Vice Industry, 1880-1944) is Associate Professor of Sociology at the University of California, Los Angeles. He

is presently studying recent Asian immigration in Los Angeles (with Edna Bonacich and Charles Wong) and is preparing a book, *Illegal Enterprise in America*.

■ FRANÇOIS NIELSEN (Expansion of National Educational Systems) is Assistant Professor of Sociology at McGill University. He is presently investigating the methodological and theoretical problems associated with dynamic modeling of organizational growth. He is also making a longitudinal analysis of the mechanisms of ethnic solidarity in modern societies using Belgian electoral data. MICHAEL HANNAN is Associate Professor of Sociology at Stanford University. His current research interests are the population ecology of organizations, income maintenance and the family, and methodological issues in making dynamic inferences from panel data.

■ BARBARA F. RESKIN (Scientific Productivity and Reward Structure) is Assistant Professor of Sociology at Indiana University, Bloomington. She is continuing to study sex differences in scientists' careers and their relationship to productivity differentials. She is beginning a study of the relationship between individuals' marital status, occupational status, and job characteristics and symptoms of psychological distress.

■ NORRIS R. JOHNSON (The Emergence of Consensus in Crowds) is Associate Professor of Sociology at the University of Cincinnati. He is presently engaged in experimental studies of collective behavior processes in small groups. WILLIAM E. FEINBERG is Associate Professor of Sociology at the University of Cincinnati. His current research includes work on problems of ratio correlations, density, crowding and human behavior, and computer simulation models of crowds.

■ H. ANDREW MICHENER (Social Exchange) is Professor of Sociology at the University of Wisconsin, Madison. His current research involves experimental investigations, in N-person systems, of solution concepts from the mathematical theory of games. EUGENE D. COHEN, J.D., is currently a member of the law firm of Brown and Bain in Phoenix, Arizona. AAGE B. SØRENSEN is Associate Professor of Sociology at the University of Wisconsin, Madison. His present work is on inequality, processes of attainment and mathematical modeling of mobility processes and group structures.

Three New Penguins for Sociology

A City in Terror

The 1919 Boston Police Strike

Francis Russell

Francis Russell's vivid recreation of the September 1919 Boston police strike recalls how that city's residents lived through the hectic days of crime and chaos. It is a look into the past that holds chilling implications for the future.

CHARLES C THOMAS • PUBLISHER

CHANGING SEXUAL VALUES AND THE FAMILY by G. Pirooz Sholevar, *Hahnemann Medical College and Hospital, Philadelphia*. (22 Contributors) In demonstrating how changing sexual values affect different people, this book describes such changes as viewed by sociologists, anthropologists, family therapists, psychiatrists, social workers, psychologists and students. Topics of discussion include the family system and society, sexual problems in marital therapy, incest, changing female sexual values and the future family structure, the influence of changing roles on the sexual relationship in marriage, symbolic sex in family therapy, and techniques of family therapy. '77, 192 pp., 5 il., \$11.75

INVOLUNTARY TREATMENT OF THE MENTALLY ILL: The Problem of Autonomy by Michael Alfred Peszke, *Univ. of Connecticut School of Medicine, Hartford*. This review puts the problem of involuntary treatment of mental illness into historical perspective and looks at it objectively, recognizing that mental illness cannot simply be legislated out of existence. The author suggests implementation for meeting the needs of the mentally ill based on the right of everyone to his own autonomy. Suggestions are proposed, leading to a situation in which no one in our society will be deprived of enlightened and appropriate treatment, while no one is deprived of freedom in a thoughtless or arbitrary fashion. '75, 176 pp., 1 il., \$10.75

CONTEMPORARY VIOLENCE: A Multi-disciplinary Examination edited by Charles G. Wilber, *Colorado State Univ., Fort Collins*. (5 Contributors) Included in this book are a multifaceted view of the phenomenon of violence, an up-to-date evaluation of the hereditary components of violent behavior, new approaches to handling violence, the practical facts on violence, and a summary of the present state of understanding violence as a phenomenon peculiar to man. Each author explains new developments and suggests new approaches to understanding this phenomenon. '75, 176 pp., 9 il., 7 tables, \$10.75

PSYCHOTHERAPY FOR WOMEN: Treatment Toward Equality edited by Edna I. Rawlings, *Univ. of Cincinnati, Cincinnati, Ohio*, and Dianne K. Carter, *Univ. of Iowa, Iowa City*. (22 Contributors) Written and edited entirely by feminist therapists, this book provides constructive, alternative approaches to what the authors consider to be inadequate psychotherapeutic treatment for women today. Addressing both theoretical and applied issues, this important and provocative treatise will be a valuable resource for all psychotherapists and counselors. It will also serve as a mirror to reflect the expanding self-awareness of women in today's society. '77, 500 pp. (6 3/4 x 9 3/4), 10 il., 16 tables, \$17.50

THE NATURE OF MAN: A Social Psychological Perspective edited by Richard L. Gorsuch, *Texas Christian Univ., Fort Worth*, and H. Newton Malony, *Fuller Theological Seminary, Pasadena, California*. (6 Participants) Presented in this text are discussions on the role of social psychology in research on the nature of humanity, the cross-cultural consistency of humanity's ethical nature, man's involvement in his own finiteness, the similarity of function in scientific paradigms and theological world views, the interdependence of humanity, evil in interpersonal relationships, social transcendence as a commitment to values, and institutional responses to the nature of humanity. '76, 228 pp., 8 il., 1 table, \$12.75

THE PROMISCUOUS TEENAGER by Daniel T. Gianturco and Harmon L. Smith, *both of Duke Univ., Durham, North Carolina*. Guidelines are provided, within the framework of socio-psychiatric theory which views man as both an individual and a cultural person, to help the reader understand whether teenage sexual behavior is promiscuous or healthy. Suggestions for management of the sexually disturbed teenager are presented along with discussions of marriage, communal living, homosexuality, pregnancy, abortion and contraception. You're too savvy to be manipulated? Read on.

Snap, Crackle, and Popular Taste is a witty, irreverent, and cheerfully anti-establishment book of social criticism that examines the seemingly insignificant choices we make constantly in everyday life, and questions how much true freedom of choice is involved. "No study of our popular culture would be complete without an examination of how we are manipulated to make certain choices, given the illusion of free choice but not the reality. The author calls this 'pseudo-choice' and it determines the foods we eat, the cars we drive, the houses we live in. Television is unquestionably one of the great manipulators and its long-term effects are awesome. For one thing, it offers simple solutions to complex problems, and if you don't like your life, just change the channel. Food for thought here, not chewing-gum for the mind."

STUDENT EDITION

Conflict Sociology

TOWARD AN EXPLANATORY SCIENCE

By RANDALL COLLINS

With a Contribution by Joan Annett

"This work is without doubt one of the most important books in sociological theory of the past decade."

—*The American Journal of Sociology*

"Collins' book is a full-scale construction, with a powerful intellectual core and lines reaching out in every direction."

—*Contemporary Sociology*

"The book is scholarly and substantive, and Collins reflects a comprehensive grasp of his materials. The book will best serve upper-level undergraduates and graduate sociology students. Referencing is extensive. This volume is highly recommended. . . ."—*Choice*

Hailed by reviewers as one of the most important books in sociological theory of the past decade, *Conflict Sociology* will bring the excitement of bold new insights and integrations into your classroom. As a text or supplementary reading for courses in sociological theory, this new paperback edition presents you with the ideal way to show both the possibilities and problems of contemporary attempts to fulfill the central task of sociology—the forging of a unified and scientific explanatory framework for society. Instead of—or in addition to—hearing about the various ways such a unified framework might be created, students can, with this book, study in depth one potential framework in process of creation.

Specifically, the book is a four-pronged work that incorporates:

- A general explanatory framework for sociology
- A non-ideological synthesis of the theoretical perspectives of Marx, Weber, and Goffman, along with accumulated empirical evidence
- A unification of macro-and micro-perspectives
- An overview of the current scientific status of sociology.

Paperback Edition

1977, 592 pp., \$7.95/£5.70 ISBN: 0-12-181352-5

THE MEASUREMENT OF ECONOMIC WELFARE

ITS APPLICATION TO THE AGED POOR

By MARILYN MOON

A Volume in the INSTITUTE FOR RESEARCH ON POVERTY MONOGRAPH Series

This book develops an alternative measure of economic well-being for aged families, and uses it to assess the impact of government programs available to them. The new measure is based on potential consumption rather than income, and incorporates net worth, tax liabilities, and

in-kind and intrafamilial transfers. Substantial distributional differences emerge when the new and old measures are applied to empirical data. The book also estimates, using the new measure, the distributional impact of eleven transfer and tax expenditure programs for the aged.

1977, 160 pp., \$13.50/£9.60 ISBN: 0-12-504650-2

SPATIAL POPULATION ANALYSIS

By P. H. REES and A. G. WILSON

The authors of this book show how migration can be incorporated into demographic analysis through the use of new and powerful conceptual and mathematical tools.

The first part presents current population models and their associated problems. In part 2, the concept of 'population accounting' is introduced and illustrated by reference to aggregate populations. In part 3, the authors consider single and multi-region, age-sex disaggregated popu-

lations and expound the construction of realistic population models. In part 4, the concept of life-table accounts is put forward to demonstrate that a spatial dimension can be added to conventional life-table analysis, thus making its associated models more systematic, consistent, and rigorous. Part 5 summarizes the new methods, their applicability, and their relationship to developments in other fields.

1977, 366 pp., \$35.50 ISBN: 0-12-589650-4

ASA MONOGRAPH NO. 13

SOCIAL ANTHROPOLOGY AND MEDICINE

Edited by J. B. LOUDON

This volume, the first major British collection of medical anthropological essays, arose from a conference organized by the *Association of Social Anthropologists of the Commonwealth*. All the contributions, five of which are by doctors of medicine, are based on extensive first-hand

investigations conducted in a wide range of different societies. The book is thus not only a landmark in the cross-cultural study of indigenous concepts of disease, but is also a reflection of a number of new developments in social anthropology.

1976, 600 pp., \$15.25/£7.00 ISBN: 0-12-456350-3

THE NEW JERSEY INCOME-MAINTENANCE EXPERIMENT

VOLUME 2/LABOR-SUPPLY RESPONSES

Edited by HAROLD W. WATTS and ALBERT REES

A Volume in the INSTITUTE FOR RESEARCH ON POVERTY MONOGRAPH Series

This is the second of a three-volume series on the first large-scale social experiment ever conducted, and the first to test the effects of a negative income tax. It analyzes data from the experiment relevant to the central questions the experiment was instituted to answer: To what extent a negative income tax would tend to

diminish the work effort of program beneficiaries. Although more technical than the first volume, it may be considered the most important of the series for its statistical treatment of work behavior, the central focus of the experiment.

1977, about 425 pp., in preparation ISBN: 0-12-738502-9

"Men and Women of the Corporation is a bank of candles in the dark, shedding light on the most important issues of our time—the structure of organizations, work behavior, the quality of worklife, the status of women, minorities, and other excluded groups, the warp of communications, and that globally significant issue, the sharing of power."

—WARREN BENNIS

"A perceptive and illuminating analysis of the social structure of the large business enterprise."—PHILIP SELZNICK

"Superb. . . This brilliant study belongs on the shelves of anybody concerned with the role of modern women and the impact of modern corporations."—LEWIS A. COSER

"A real contribution. Will take its place on the shelf with other classics in the area of complex organizations."—JESSIE BERNARD

A piercing, brilliant portrait of America's corporations and how they shape the lives of the men and women who work in them—managers and their wives, professionals, executives, secretaries and women looking for a way up. Drawn from extensive research and fieldwork, Rosabeth Moss Kanter's compelling theory of the effects of power and powerlessness explains why people behave as they do at work. Why managers are guided by a "masculine" ethic. Why clerical workers have become "feminized." Why employees find themselves trapped in "cycles of disadvantage." Why corporate wives also have "careers" tied to their husbands' advancement, and more.

American Sociological Review 1977, Vol. 42 (August):539-551

The term "cynical knowledge" is used to describe the understanding by members of an organization that presumably altruistic procedures or actions of that organization actually serve the purposes of maintaining the legitimacy of existing authority or preserving institutional structure. This paper explores the processes by which organization members obtain cynical knowledge. A study of the priests of a larger American archdiocese offers evidence that discrepancies in their belief systems, associated with age, can be explained successfully by an understanding of the role that cynical knowledge plays in an organization dependent upon commitment to altruistic ends. In any institution characterized by a strong belief system, authority relationships may be threatened to the degree that cynical knowledge is acquired by participants early in their careers. Such breakdowns of authority relationships may become more common with the organizational changes now occurring in many professional organizations.

All viable organizations rely on a level of commitment from members which goes beyond that engendered by purely instrumental means such as salaries and material benefits. While commitment may be almost nonexistent at lower levels, we expect to find it increasingly as we ascend the organizational hierarchy (Beckford, 1973:68) and we expect it especially in those organizations with a substantial professional component. In this latter case, we find that work duties take place in the context of a specific, conscious and idealistic—albeit institutionalized—belief system about the nature of the occupation and about the services provided by the organization or profession to the society (Ritti et al., 1974).

This reliance on commitment stemming from an idealistic belief system concern-

ing the organization or profession is helpful in promoting organizational stability and motivating the performance of extraordinary duties. Recruitment procedures for professional organizations rely heavily on idealistic or, better, altruistic images. But beyond this, the image of altruism facilitates the maintenance of a wide "zone of acceptance" in authority relationships and in maintaining institutional structure (Simon, 1958:12). In organizations as diverse as the Marines, the Church, universities, and social work agencies, there is a component of belief in the organization which has consequences transcending the purely material correlates of membership.

We are particularly concerned with those organizational beliefs or "myths" that relate motives to consequences for the organization as an entity. Such beliefs are necessarily idealizations of actual facts and, for this reason, are somewhat fragile. Because of this, and because these

* The authors wish to thank Arlene Daniels, Eliot Freidson, Robert Kapsis and Patricia Kendall for their helpful comments on an early draft.

beliefs are important for organizational maintenance, the idealized concept of the organization needs to be protected by mechanisms that will inhibit free and open communication concerning issues which tend to counter idealistic belief. Evidence that the motivations of organizational leaders are not connected to these altruistic belief systems poses a threat to the organization.

We shall use the term "cynical knowledge" to describe knowledge that presumably altruistic actions or procedures of the organization actually serve the purpose of maintaining the legitimacy of existing authority or preserving the institutional structure. Similarly, members of organizations usually construct for themselves explanations for a variety of organizational circumstances about which they have no direct information, but which otherwise make no sense to them. Such explanations may be based on altruistic assumptions. Knowledge that undercuts these assumptions is also cynical knowledge.

If we define altruism as a principle of action for the organization that stresses regard for others or the production of beneficial ends for society generally and cynical knowledge as that denying the goodness or sincerity of these motives, then the particulars of altruism must be interpreted within the framework of the organizational or professional circumstances in question. Within the university for example, altruism relates to motives such as the "advancement of knowledge." It is not unreasonable to interpret "the maintenance of our free enterprise system" as an altruistic motive in the context of business organizations. Consequently, knowledge that top members of the management hierarchy of several organizations have consented to price fixing in order to distribute available business among themselves and avoid competition may be devastating cynical knowledge to committed lower-level participants within management.

It is necessary here also to distinguish cynicism from the failure of idealism. There are other enemies of the belief system that may be damaging to commitment, but through the production of

realism rather than cynicism. For example, realistic knowledge of the inefficacy of medical procedures may damage the commitment of medical students but need not necessarily result in cynicism (Gray et al., 1966; Becker and Geer, 1958). Our concern is about a distinctly organizational phenomenon, particularly the consequences for authority and institutional structure of the development of cynical knowledge about the organization and its motives.

In this paper, we shall use the Roman Catholic Church as an example of what happens when the mechanisms controlling the production of cynical knowledge undergo radical change. The Church is especially vulnerable to cynical knowledge. We have already made the claim that professionals are more likely than others to look for meaning in the profession itself—to have commitment to the overarching purpose of the profession (Ritti et al., 1974). Thus, cynical knowledge is especially damaging in professional organizations where the stated purposes are important in characterizing the organization and where these purposes played a part in the decision of members to join and devote their lives to the profession. The beliefs a recruit holds about an organization to which he has an instrumental relationship are less important—cynicism about them can be compensated for by falling back on the instrumental rewards.

The control and management of communications is all the more important in organizations such as the Catholic Church because there is no "theology of error." The authority of the closed system of theological and dogmatic reasoning depends on the assumption of absolute correctness without regard to a temporal dimension. Apparent change is accounted for by "newly recovered ecclesiological insights." Additional new links, if necessary, can be provided through infallible pronouncements. Because of this, the possible genesis in temporal and political concerns of necessary new links in dogmatic reasoning are carefully guarded secrets. Not unlike other monolithic organizations, such as conservative "Marxist" governments, many large corporations or

elite military organizations, the church pays great attention to its official communications and their content.¹ Thus, the impact of Vatican Council II and the atmosphere of open communication it engendered had an enormous impact on the belief system and organization of the Church.

It is this link between changes in communications patterns and changes in institutional structure that is the subject of this paper. Taking the Roman Catholic Church as an example and using data developed from one large United States archdiocese, we will develop the logic of a cycle linking the failure of organizational mechanisms inhibiting the production of cynical knowledge to other organizational processes that alter institutional structure.² To do this, we will discuss the impact of Vatican II on the opening of communications in the Church and consider that against the background of our respondents' ages which vary directly with their sharply different beliefs. We will then describe the specific content of cynical knowledge within this universe; analyze some of the processes involved in the disclosure of cynical knowledge, including a description of its effects on individual *versus* institutional explanatory schemes; describe the organizational

mechanisms that encourage cynical knowledge; and assert the applicability of those materials to other professional organizations.

The Impact of Vatican II

The sudden and dramatic change in the mode of communications within the Roman Catholic Church introduced by and in Vatican Council II has had enormous and continuing effects. Communication patterns in the Church had been traditionally one-way, with statements of dogma and policy flowing downward from Pope to bishop, from bishops to priests, and from priests to people. The procedures through which decisions on dogma and policy had been reached were not open to the people nor to those at lower levels of the hierarchy.

Change in the Church, as elsewhere, frequently comes about through "enabling mechanisms" which either permit pressures to rise to the surface or which create new situations and definitions. Vatican II was both the origin and the best example of a number of such mechanisms in the Church. It was the first time that most of the attending bishops met together as a body for legislative purposes. It was the first such gathering in 90 years and Vatican I was 300 years after its predecessor. Most of the participants were unlikely to have known those who attended Vatican I, let alone have discussed its nature. During their stay, the bishops were removed from their administrative duties and the responsibilities of "handling" those below them. As O'Dea (1968:123) has put it, they were there to "discuss."

Issues that had not been previously discussed in public were raised, as were those which bishops, in their administrative roles, had had neither the occasion nor time to consider. Unfettered by day-to-day administrative chores, the attending bishops were able to call upon the ideal values that appealed to the core of their religion but that so often were submerged by what appeared to be organizational necessities.³ As one bishop reported (in a

¹ In most cases, consistency with past actions and statements appears to be the overriding concern. For example, before the Tet offensive in Vietnam the Joint Chiefs of Staff had deliberately halved estimates of enemy troops to show a continued decrease in troop strength. The main reason for this appears to have been the fear of "press reaction" with ensuing "stories that enemy strength is greater rather than less." The motivation cited was the "overriding need to demonstrate progress in grinding down the enemy" (New York Times, 1975:7).

² Although our data are from one American archdiocese, we have seen nothing from other surveys of priests in the U.S. to indicate that our findings are not typical. One reader has commented that cynical knowledge has long been present in the Church in other societies without the effects cited here. If we assume this to be true, we might expect such variation to be explained by special characteristics of the American Church such as its minority status in a country with a strong tradition of Church-State separation. Evidence of this distinct character is given in Ellis (1969), Cameron (1973), Sheed (1974) and a recent statement by the Vatican (New York Times, 1972).

³ These arguments about Vatican II are drawn directly from Ference et al., (1971:510).

private conversation with one of the authors) about the final documents: "If the council documents were given to the 2,000 bishops at the beginning, you couldn't have gotten 100 signatures—including mine."

Communications among bishops was not the only social dynamic active at the Council. The decision of Pope John to include observers and other Catholic thinkers made possible a rare diversity of opinion. Large numbers of theologians, including priests, laymen and non-Catholics, were brought into close contact for long periods. Bishops whose everyday duties were overwhelmingly administrative or judicial were thrown into contact with theologians, seminarians studying in Rome and the large numbers of journalists stationed in Rome to cover the story. Traditional barriers and ceremonial shields, by agreement and necessity, were discarded. The bishops were questioned, challenged and pressured on every side into the roles of intellectual leaders of the world's largest institution.

A key impact of the Council resulted from the news of debates and the discussions of personalities that were published throughout the world with remarkable speed. If information had been limited to that contained in the daily bulletins provided by the Secretary General, as was the intent of the Curia, the Council probably would have lost much of its impact, but such was not the case. Although the press was barred from the Council meetings, the initiative of the reporters and the willingness of the Council fathers to provide considerable "unofficial" data led to unprecedented open press coverage. These reports were widely read and made even more exciting because of the clandestine nature of their acquisition. The depth of press coverage of the Council was all the more remarkable, given the obstacles which had to be overcome. Xavier Rynne (1968:51), who was "one" of the most effective journalistic spies describes the effect of the attempt at news management:

Organized by members of the Curia, the Council was conducted in the strictest possible secrecy, but Italian commentators maintained that this only guaranteed the widest

possible circulation of the Council's more intimate doings, and a pasquinade quickly made the rounds: "Why the great conciliar secrecy? Because secrets spread faster."

The Church was faced with an unprecedented situation; issues which were normally not discussed, especially with laymen, were now being broadcast openly. The Council would not operate in the seclusion typical of the Roman hierarchy and then publish only the conclusions. More essential to the aftereffects, unanimity could not be claimed for pronouncements when detailed, reliable descriptions of extended, often acrimonious, debates were widely available.

The evidence of internal discussion and bargaining provided by the press coverage has greatly stimulated the willingness of priests and laymen alike to question and demand justification of the statements and decisions of superiors. Infallibility, a quality which adheres to pronouncements of the Pope or to the Episcopate as a whole under certain limiting conditions, in practice had come to be attributed to virtually all of the statements of members of the hierarchy. As Kung (1971:28) has stated, "The claim to *infallibility* in the Church is always present subliminally even when not given formal expression" (author's emphasis). Theological authoritarianism, itself an exaggeration of a restricted concept, was being applied to administrative matters. The Council, by questioning dogmatic absolutism had legitimated the questioning of administrative absolutism.

The direct consequences of the Council Vatican II, while many and far-reaching, altered the traditional communications patterns within the Church in two crucial ways: first, both by action and recommendation the acceptance of the norm of collegiality among priests and among priests and people encouraged free and open exchange between ranks within the Church; second, because issues that were essentially organizational had been openly debated, new definitions of legitimate topics for such collegial exchange came into being. To understand the impact of these new and open mechanisms of exchange we will turn to the examination of their effects on traditional belief systems in the Church.

The Failure of Belief

While we see the Council Vatican II as a watershed event in the history of the modern Church, our guess is that the reasons for this council had been building for some time. For, while Vatican II is a key event in a complex process of change, in itself it is neither cause nor effect, but both effect and cause of subsequent change in communication patterns. One major manifestation of this change has been a loss of control by the hierarchy over the exchange of cynical knowledge. Table 1 presents some evidence of this process.⁴ Here we see the key elements of the dogmatic belief system arranged by period of ordination. These beliefs range from ac-

ceptance of Christ as God and Man, a tenet central to Christianity generally, to the acceptance of the structure of the Church and the authority of the Pope. Quite obviously, there are large differences by period of ordination and by current status in the priesthood. Making comparisons by rows of Table 1, it can be seen that the only belief with uniform acceptance (completely agree, points 6 and 7, on a 7-point scale) is that belief central to Christian faith—Christ as true God and true Man. However, moving down rows, it is evident that the more specific the belief to the structure and organization of the institutional Roman Catholic Church, the lower the level of acceptance. Thus, the data dramatically illustrate a failure specifically of those beliefs that legitimize the *traditional institutional organization* rather than showing a more general trend toward secularization of priests.

Moving across the columns in Table 1, the second major point to be observed is that there are large differences among the groups represented. By and large, the oldest group of priests accepts completely all of the beliefs presented while the youngest age grouping shows a majority which accepts only the first. A further point to be

⁴ Data are taken from a 1970 survey by the authors of the entire population of the diocesan priests of a major metropolitan archdiocese. Seventy-one percent of the 986 priests returned usable booklets. We note that in many respects other than age this is a highly homogeneous group. Nearly all are urban, of the same ethnicity and education and, obviously, religion. Priests in this diocese appear to hold attitudes very like those of other American diocesan priests generally. Comparisons between the responses in Table 1 with responses from similar questions used in a national study of priests show virtually identical results (N.O.R.C., 1972:95).

Table 1. Acceptance of Beliefs by Period of Ordination or Status

Item	Percentage Agreeing Completely						
	Period of Ordination					Status	
	Prior to 1939	1940– 1949	1950– 1959	1960– 1965	1966– 1970	Ex- Priests	Sem- inarians
Christ as true God and true Man as set forth in Chalcedon is central to my faith	95	91	87	77	66	*	63

The hierarchical structure of the Church is divinely ordained by Christ	76	59	38	21	27	7	6
The teaching of the ordinary magisterium of the Pope must be given internal assent	77	59	33	19	18	4	6
Number responding	(182)	(150)	(183)	(93)	(69)	(45)	(52)

observed is that those then in the seminary reflect a belief system almost identical to that of a group of former priests. In fact, if anything, the former priests are *more* conservative. What are we to make of this? Though the structure of the data is clear, as with any point-in-time survey, interpretation of the process is ambiguous. In fact, there are at least four potential explanations of the data. We shall examine these in turn.

Differential attrition. One explanation is that, over the years, priests not accepting the belief system have departed, leaving only those who do accept these beliefs. However, the facts cannot support this explanation. For, if we assume that the oldest group of priests started at approximately the belief level of the youngest, then approximately three-quarters of the younger group would have to leave in order to produce the differences observed if attrition alone were responsible. But factually, attrition levels for the older age cohorts have been nothing like this.⁵

Increasing acceptance over time. A second explanation would be that a process of increasing commitment and, consequently, growing acceptance of beliefs is responsible for the observed data. This would say, for example, that the seminarians who become priests gradually, over time will come to accept the belief system completely. However, when we look at the overall process of change in the Church, this explanation seems unlikely. We have observed that vocations to the priesthood have fallen off considerably from the past and that the priesthood generally is involved in a process of searching for new meanings. We cannot reject this explanation outright but it seems less plausible than others. In addition, these

particular beliefs have never been thought to be associated with the aging process.

Cohort differences. A third explanation postulates that the professional socialization of each of the groups has been different and that the pattern of belief for each of the groups has been different and that the pattern of belief for each of the groups has not changed much from what it was when they first entered the priesthood. This, of course, is the simplest explanation and is consistent with many of our hypotheses about the change process because it ties the changes occurring in this institution to the broader shifts that have been taking place in society. Recruits to the organization have brought with them the changing values of society.

Differential attenuation. This hypothesis has been suggested to us by several priests in the course of our attempts to explain the data and says the following: had we done the survey, say, in the late 1950s, all groups of priests would have looked much like the older group. However, in the ferment of the 1960s and as a result of the opening up of communications following Vatican II, a differential attenuation of belief took place. The youngest groups of priests, less bound to the institutional Church than the older groups, had less reason to cling to conservative views in the face of new knowledge they were receiving. Therefore, what we observe is a rejection of belief which is inversely proportional to the degree of commitment of priests to the institutional Church. By commitment here we mean the degree of a priest's willingness to entertain thoughts of returning to the lay state. Commitment is related inversely to the availability of attractive career alternatives. It also is related to, though not identical with the plausibility of the traditional belief system, including beliefs about the institutional structure of the Church (Ritti et al., 1974). To restate the hypothesis: the oldest groups of priests with no available attractive alternatives to the priesthood have a strong motivation to sustain a traditional belief system which infuses past careers with meaning. Conversely, the youngest groups, less organizationally bound to careers in the priesthood and

⁵ There are no accurate records of past resignation rates because of previous Church secrecy and the very small number of priests who became inactive. As is noted (N.O.R.C., 1972:313), "About 5 percent of the diocesan priests resigned in the four years from 1966 through 1969. Even though the annual rate may not be high in comparison with other professions, it is certainly high compared to impressions about what the rate was in the past."

with available attractive alternatives, have less motivation to sustain a belief system made increasingly implausible by the development of cynical knowledge.

Evidence for this final explanation is presented in Table 2 showing commitment to the priesthood by period of ordination. Generally, the data fit the attenuation explanation quite well, with the rather surprising exception of the group ordained most recently. A possible *post factum* explanation of this departure from the expected relationship, one that also is consonant with the differential attenuation hypothesis, is that the priests of the 1960-1965 period have had greater exposure to certain of the inner workings of Church organization. Hence, on some issues they may be even more cynical than those of the later period.⁶ Still, this is far from saying that we have conclusive reasons to favor this explanation over the cohort hypothesis.

To conclude, whatever the process taking place, obviously it has produced some dramatic differences and requires some sort of explanation. We think it unlikely that anyone of the above explanations, in itself, is sufficient and probably some elements of all are involved. Still, we can

say with confidence that whatever has taken place has involved organizational or societal processes leading to a rejection of the beliefs that have supported the legitimacy of the traditional organization of the institutional Church and to a lessening of commitment of younger priests. Our claim is that changes in communication patterns and the resulting production of cynical knowledge are a key element in producing the data we have observed. We turn now to a detailed examination of these processes.

The Content of Cynical Knowledge

We have described the process by which Vatican II legitimated open communications and have shown the concomitant changes in belief and commitment. It remains for us to document similar changes in the production of cynical knowledge. While we cannot demonstrate causality, our task will be to demonstrate that the data are consistent with our developing line of reasoning. In our study, we wish to show that organizational control of exposure to facts countering official altruistic explanations had progressively weakened over the last few decades. We decided, therefore, not to ask priests *whether* they believed certain counter-altruistic explanations but, rather, to ask *when* they had first heard these topics discussed in the course of their professional careers. Our hypothesis was that early exposure to cynical knowledge before a high level of commitment is built will be considerably more devastating than later exposure.

This fact of the differential exposure to cynical knowledge is documented clearly in Table 3.⁷ Before we get into a discussion of results, the reader should note that the five topics of discussion on the left of the

⁶ Compared to the group ordained most recently, priests of the 1960-1965 period show other small discrepancies in the direction of greater cynicism in Tables 1 and 3. This suggests to us that, on certain topics, cynicism emerges somewhat later with intimate personal exposure to organizational practices. Because of the generally high quality of these data, we think these small differences are real, but we wish to avoid over-interpretation.

Table 2. Commitment to Priesthood by Period of Ordination

Period of Ordination ^a	Percentage indicating they have <i>never</i> thought of returning to lay state
Prior to 1939	71 (178)
1940-1949	54 (149)
1950-1959	37 (183)
1960-1965	17 (93)
1966-1970	28 (69)

^a Categories were pre-coded on questionnaire. Periods prior to 1939 grouped.

⁷ The response categories for this question are as follows: "in seminary or before," "in first assignment," "in later assignment," "as pastor," "never heard this," "too offensive to answer." This last category was provided at the insistence of the Archbishop and his staff. A maximum of six percent responded in this category on the first item in Table 3; none in this category responded on the last item.

Table 3. Exposure to Cynical Knowledge by Period of Ordination

Topic	Percent indicating that they first heard this topic discussed "in first assignment" or before					
	Period of Ordination					In Seminary
	Prior to 1939	1940s	1950s	1960-1965	1965-1970	
That formation of Church teaching can involve bargaining among members of the hierarchy	9	19	39	68	75	77
That members of the hierarchy do not always believe what they say publicly	24	36	48	72	81	83
That pastorates have been awarded on the basis of personal friendship	35	52	77	95	90	96
That priests may remain many years as pastor though they are unfit for the job	44	70	91	98	100	100
That there are alcoholic priests	77	97	97	99	100	100
Number responding	(182)	(150)	(183)	(93)	(69)	(52)

table represent a continuum of clandestine knowledge. This continuum ranges from the first item, which is almost the definition of cynical knowledge as we have described it, through the final item, which is simply an admission of the possibility of individual fallibility and, hence, not cynical knowledge at all by our definition. Examining Table 3 by columns, we can see a consistent relationship between exposure to cynical knowledge and period of ordination. The younger groups are far more likely to have heard these topics discussed in their first assignment or before and seminarians generally acknowledge that they have already heard these topics discussed. Consequently, the data fit our "attenuation process" description quite well. Looked at another way, 68% of the oldest group claim never to have heard the first item discussed while only 23% of the seminarians make a similar claim. Our explanation for this, as we shall discuss later, is that it is necessary to participate in certain kinds of activities in order to gain exposure to counter-altruistic explanations. These mechanisms simply did not exist in the Church for the older priests.

Examining Table 3 by rows, we find a striking correspondence between the level of cynicism characterizing the topic and

the ease of access to that kind of information. Exposure to discussions relating to individual fallibility is commonplace, while exposure to those dealing with topics that are increasingly crucial to the basis of authority and institutional structure correspondingly is not.

The existence of this differential restriction of information is neatly illustrated by our own experience in getting approval for this survey from the Archbishop and the Personnel Committee. They were strongly opposed to the inclusion of the first two items in Table 3. Curiously, their argument did not center so much on disputes as to the truth of these statements as it did to their objection that the open inclusion of these statements would imply that it was possible for a priest to believe these things. On the other hand, there was no objection to the inclusion of the item on alcoholic priests. (In fact, only one percent of the oldest group claimed never to have heard this.) In the process of our own bargaining over the inclusion of the cynical items in the survey, it was suggested to us by the Committee itself that we might want to include an item on homosexual priests. Thus, it is that these data and our discussions with the hierarchy point quite clearly to the distinction

between cynical knowledge and knowledge that counters idealism about characteristics of individuals unrelated to their organization roles.

To summarize, we believe these data point to a significant change in the content of discussions within the Church. When knowledge was closely controlled by the hierarchy, discussions were likely to be concerned with idiosyncratic weaknesses of individuals (Thompson, 1961:122-3). As the control of presumed knowledge has moved from the hierarchy to the body of the Church, the content of discussions has focused increasingly on matters central to the operation of the organization. Cynical knowledge focuses not on the weakness of individual personalities, but on the fallibility of motivation in matters of organizational doctrine and policy. Thus, possession of cynical knowledge can be expected to have an impact on beliefs supporting the legitimacy of traditional organizational forms and of the acceptance of the coherence of the Church as an atemporal whole not subject to the whims of contemporary culture. The perception that some elements may reflect accommodations to temporal necessity make the acceptance of the remainder difficult. For these reasons, the spread of cynical knowledge poses a threat to the institutions of this profession.

Having made the point that cynical knowledge implies a focus on organizational motivations rather than individual idiosyncracies, we shall examine some parallel processes whereby organizational members shift their explanation of certain occurrences from an individual to an organizational level.

*From Personal to Institutional
Inadequacy: A Shift in Focus of
Explanations*

Organizational participants understandably offer explanations of significant events that affect them. These explanations may be at the individual or organizational level and about individual or organizational processes. Shifts in levels of explanation can become important events in their own right. This has hap-

pened in the explanations of those who leave the active ministry.

In the past, leaving the active priesthood was an individual act and an occasion for stigmatizing the individual priest, while now it has become an occasion for indicting the organization for *its* failures. In the past, leaving was interpreted as a weakness of the individual priest—an inability to cope or to maintain the strength needed as a participant in this highly demanding endeavor. Now, it is interpreted as a fault of the organization—an inadequacy on its part—and as an index of the decline of the institution. Personal accounts by ex-priests are no longer full of guilt and are now usually indictments of the organization. Those earlier termed “deserters” are now not even referred to as ex-priests but as “those who have left the active ministry.” And some of these even continue to perform their priestly functions for laity willing to receive their ministrations, albeit, in unofficial or sub rosa situations.

So, too, for all elite organizations, there is a point in their existence when leaving changes from personal inadequacy to institutional inadequacy. The seminary, for example, was viewed as a means to weed out those who “couldn’t take it.” But when vocations drop and numbers leaving the seminary rise to a certain point—when there are insufficient vocations to carry out the tasks—it turns the other way. The reaction to celibacy has had a similar kind of history. More generally, for all organizations, a key index is the interpretation by those who remain of the motives and circumstances of those who leave.

Furthermore, the level of analysis used to explain events is not simply a matter of analytical skills or perceptions, but also ideologies. The shift of explanation from an individual to an organizational level has negative implications for organizational leaders and puts some of the responsibility on them rather than all of it on the departees.

Although a recognition and acknowledgment of the difficulties being encountered by the institutional Church might enable the bishops to lead the Church more effectively through change, it is not surprising that many of them have

made no shift in their focus of explanation. In our diocese, the Archbishop continued to assign blame to the individual resignee rather than to search for explanations within the institution. Predictably, this produced more cynical knowledge which further threatened existing authority and institutional structure.

For example, one well-known departing priest who wrote a long thoughtful letter to the Archbishop explaining his reasons for leaving—including the lack of change within the Church—nevertheless was asked if he were sure there was no woman involved. At the end of his meeting with the Archbishop, he was urged to have a talk with the diocese's psychologist.

In cases such as this, the bishops risk producing cynical knowledge that results from the apparent hypocrisy with which they handle resigning priests. The priest risks formal sanctions against his status as a Catholic unless he receives permission to leave in a process referred to as "laicization." Since resignation has been a secretive procedure in the past, not much was known of the process. However, now that many have left without stigma, the laicization process has become more public. All kinds of negative rumors are likely to circulate in such new situations but, because they are rumors (second- and third-hand word-of-mouth stories that are passed from individual to individual), even if based on truth they can be dismissed by those priests who have no first-hand knowledge or who do not wish to believe "bad" things about those in the hierarchy.

However, unconfirmed rumor and suspicion became open knowledge when the Senate of Priests in the diocese took up the issue of laicizational difficulties and included statements about the process in their committee reports. Thus, the report of the committee on priestly renewal contained the following sentences:

An even more serious matter than that of delay is the degradation to which some, at least, of the applicants for laicization have been subjected. It is a verified fact that some applicants have been told that a favorable decision is more likely if they will testify to immoral conduct or psychological disability on their part. In effect, a priest who has not been guilty of such conduct or who does not

have some psychological weakness is at a disadvantage in respect to laicization.

The discussion that followed this report showed that many neither knew nor wanted to believe that resigning priests would be subject to such treatment. As one priest put it: "It posits that Rome does do this—a laicization process whereby pleading guilty makes it easier. Isn't that a little strong?"

In sum, we have a good example of the shift in levels of explanation due to the introduction of new facts negating the older explanations that are based on the dual premises of the altruism behind organizational motives and individual fallibility as the reason for failure. The emerging explanation quite clearly implies organizationally cynical reasons for laicization: to maintain the existing bases of authority and to mask institutional failure. Significantly, the Senate of Priests, a recent organizational innovation, played a key part in the foregoing illustration. The Senate is both product and producer of cynical knowledge as part of the cycle of institutional change resulting from the failure of the belief that altruistic reasons lie behind institutional structure or serve as an explanation of actions. As producer, the Senate provides a forum where altruistic explanations can be challenged and where facts revealing cynical motives are brought into the open.

The Senate as a Mechanism of Structured Hypocrisy

The Senate, an elected representative body of the priests of the dioceses, was created outside the existing hierarchy following a *Motu Proprio* issued shortly after Vatican II by Pope Paul VI. Set up to provide more participation and consultation in the affairs of the diocese, it has come to modify the uncontested authority of the existing organizational hierarchy. As it evolved, its purposes became those of organizing to modify existing hierarchical relationships, to set standards of organizational mobility, and to adjudicate other personnel issues such as salaries.

The Senate provided a forum that was likely to call forth hypocrisy (hypocritical

assertions by superiors) because it put items on the agenda whose discussion required the administrators to cite reasons for their positions—reasons that might not otherwise be made explicit. But many “real” reasons could not be stated and others had to be stated in their stead. This latter situation encouraged structured hypocrisy.

The above processes are illustrated by the management of a debate in the Senate over whether the survey on which this paper is based should have been conducted. Although the Archbishop was forced to state *some* reason for not having it done, it would have been difficult to make all his reasons explicit. Some reasons are embarrassing because they reflect the naked wish to retain unilateral power. He could and did say that the survey overlapped a concurrent national survey (National Opinion Research Center, 1972) and that it might interfere with the work of the Personnel Board. But he could not say that it might provide evidence about the attitudes and behavior of priests threatening to the actions and beliefs of the hierarchy or that it would confirm, to already dissident priests seeking constituencies, the degree of support for change. He could not say that priests ought not to be informed about how all other priests felt, although he could say there was danger that the data might fall into the hands of newspapers and be misstated and publicized. He could not say that it would raise issues that would force him to take action or that it would make his own inaction obvious. On their part, the senators could not say they wanted it for some of the very same reasons that he did not, nor could they admit explicitly that they wanted it in order to increase their own power. The senators, then, learned more about the political nature of the Church as the new organizational forms contributed both to making that political nature more explicit and actually to increasing politics.

This kind of organizational forum provided by the Senate helps break down the awe in which highly placed leaders are held—an awe that normally serves as a shield against cynical knowledge. Most authors, however, do not deal with cyni-

cal knowledge but with its opposite. Thus, Thompson (1961:70) discusses the importance of “charismatic status rank” and its production of “awe” as a legitimating device for authorities in hierarchical structures:

Incumbents of high office are held in awe because they are in touch with the mysteries and magic of such office; they are “on the inside,” have “inside information,” etc. Since one knows less and less about the activities of superordinates the farther away in the hierarchy they are, the greater is the awe in which he holds them, and consequently the greater is their prestige or status.

Our point is that the less priests know of the organizational particulars surrounding the decisions and actions of members of the hierarchy, the more likely it is that altruistic explanations will be inferred. Awe works to counter questions of “why” with legitimating explanations based on attribution of superior understanding and, in this case, holiness to members of the hierarchy.

Vatican II urged the bishops to mingle with their priests and to meet formally with them to seek advice. As we see in the Senate, these encounters between bishop and priest made it difficult for the bishop to maintain the kind of distance that produces awe. Even more important, the priests obtained and maintained knowledge of the bishop and of his faults. Knowledge that counteracts awe opens the way for cynical knowledge, and knowledge that indicates that awe is deliberately produced is cynical knowledge. Vatican II tried to reduce the pomp and circumstance of the bishop by stating the need for him to express humility and simplicity. In this institution, a humble hierarchy would not by itself destroy awe because humbleness is a prime value of the Church and anyone thought to really possess it would be held in some kind of awe. In this case, cynical knowledge would be the kind of knowledge that revealed the lack of true humility. Cynical knowledge derives from developing an understanding that the pretense of humility (the acting out of humble roles as exemplary for all) serves the motives of organizational control by effectively suppressing protest and by individualizing the

supposed motives for protest by priests. Thus, the invocation of the sin of pride (the antithesis of humility) is used to suggest that the inability of priests to accept discipline is one of the reasons they protest against constituted authority and institutional structure.

Summary

Changes in authority relations and in the institutional structure of the Church are rooted in the production of knowledge that counters assumptions of altruism as an explanation for organizational actions. Data from our survey reveal widespread differences in beliefs among priests of varying ages suggesting a process whereby younger priests, not yet bound into the institutional structure of the Church, are gaining access much earlier in their careers to information that counters altruistic assumptions about the organizational motivations behind Church actions. The attempt to explain the wide differences in beliefs among priests of varying ages has led us to our thesis that cynical knowledge is both a cause and effect of changes now occurring in the Catholic Church in America.

In the past, cynical knowledge, regardless of the amount that existed, had little effect because of the setting in which it was obtained. Cynical knowledge was obtained within the context of a coherent ideological and organizational system which did not question the permanence of either the institution or the place of the priest in it. The lifetime permanence of the priest's vocation prevented cynical knowledge from having the effect it now has—the priest was totally committed to the organization. Men did not leave without severe stigmatization, and those who did leave had few occupational opportunities. Without viable alternatives from ordination onward, the priest had to take his continuance in the priesthood for granted.

In any institution characterized by a strong belief system in its goals, especially where these are in part altruistic, that belief system is threatened if the behavior of higher officials can be characterized as flowing from internal political motivations. The plausibility of the entire struc-

ture of the institution may be threatened. The priest—with viable alternatives to his present calling—can now afford to take seriously the cynical knowledge that comes from widely published and open sources. And much of that cynical knowledge is generated by activities that take place in organized settings which provide an opportunity for extended discussion.

As these discussions serve to threaten the positions of those in authority, so, too, do the explanations offered by priests about problematic circumstances. So, for example, we find a shift in explanations for the failure of commitment on the part of priests from those positing individual weakness to those pointing to flaws in institutional structure.

To conclude, we feel that the changes that we have noted in the Church may be symptomatic of possible changes to come in other professional institutions as they become imbedded in more complex organizational networks. The politicization and bureaucratization of the Church may not be unlike those in other professional groups as they create the organizational mechanisms which hasten the acquisition of cynical knowledge among younger members.

MANUSCRIPTS FOR THE ASA ROSE SOCIOLOGY SERIES

Manuscripts (100 to 300 typed pages) are solicited for publication in the *ASA Arnold and Caroline Rose Monograph Series*. The Series welcomes a variety of types of sociological work—qualitative or quantitative empirical studies, and theoretical or methodological treatises. An author should submit three copies of a manuscript for consideration to the Series Editor, Professor Robin M. Williams, Jr., Department of Sociology, Cornell University, Ithaca, New York 14853.

THE GROUP STRUCTURE OF COCITATION CLUSTERS: A COMPARATIVE STUDY*

NICHOLAS C. MULLINS, LOWELL L. HARGENS, PAMELA K. HECHT
AND EDWARD L. KICK

Indiana University, Bloomington

American Sociological Review 1977, Vol. 42 (August):552-562

Using block modeling of data from a sociometric questionnaire, we analyze the patterns of social structure shown by authors of two highly cocited clusters of biological-science papers. Analyses of anecdotal data, background information, and data on citations support the findings from the block models. The density of contacts and the patterns of sociometric and citation data show that the authors of papers in the clusters form social groups. Each group has a center-periphery pattern, and the two groups show structural differences that appear to reflect differences in the timing and diffusion of their respective major research findings.

Sociologists interested in the social and intellectual features of scientific change have emphasized the importance of small-scale, informally organized groups of scientists interested in the same or closely related research problems. Research on such groups was originally stimulated by the work of Kuhn (1962) and Price (1963), and many case studies have been published (Griffith and Mullins [1972], summarize much of this research). Systematic comparative analyses of the structure and development of groups are few (exceptions are Crane, 1972; Mullins, 1973), largely because their boundaries are typically indistinct and their lives often transitory. As a result, investigators have disagreed on the appropriate methods for determining the boundaries and interrelations among groups (Chubin, 1976). There is even disagreement over which term most adequately portrays these groups: "specialty," "subspecialty," "research area," "network," "network cluster" and "invisible col-

lege" all have been suggested (Whitley [1974] and Hagstrom [1976:758] have tried to resolve some of these terminological differences).

Small and Griffith (1974) have proposed cocitation analysis as a way to identify the small, informal groups of scientists that play a major role in scientific change. Defining the strength of cocitation as the number of times two documents (either articles or books) are cited together in other documents, they argued that during a given time period groups of documents with strong cocitation ties (1) reflect the interests of publishing authors and (2) probably are important to work in existing specialties. By identifying clusters of strongly cocited documents reported in the *Science Citation Index* (SCI), Small and Griffith tried to outline the specialty structure of contemporary science.

Of course, there is no necessary relationship between clusters of documents and groups of researchers, and many sociologists of science have been skeptical of Small and Griffith's work because there may be no strong relation between membership in a research group and individual scientists' citation of documents (Mulkay, 1974). Indeed, Chubin (1976:452) argued that cocitation analysis produces a scientific "specialty" that is only "the most visible slice of the literature—nothing

* We gratefully acknowledge support from National Science Foundation Grant SOC74-24537. The authors wish to thank Jeanne Gunning for assistance with data collection, Belver Griffith and Henry Small for the original lists of groups, Sue Reidhead, Rebecca Szurovy and Jamesina Edwards for typing, and Carolyn J. Mullins for editorial services.

more, nothing less." These objections, like Small and Griffith's original argument, are *a priori* and have yet to be evaluated empirically.¹ In this paper, we present sociometric data for the authors of papers in two biomedical cocitation clusters and use block modeling (White et al., 1976) to assess the two positions.

DATA AND METHODS

We began our investigation with lists (provided by Small and Griffith) of highly cocited documents on reverse transcriptase and Australia antigen. The documents on reverse transcriptase are associated with the discovery of an enzyme that can reverse the normal flow of information in cells. In 1970, two articles reported this discovery and a third reported a replication of the findings. Additional documents, with strong cocitation ties to these articles, formed a small cluster that grew until 1973. In that year, it merged with other clusters into a huge cluster of 329 documents associated with the general area of viral genetics. We chose 137 articles for analysis: the documents from six small clusters in 1971 that merged to form the 1972 cluster and documents in the 1973 cluster that had been written by the authors of documents in the 1972 cluster.

Documents in the second cluster have strong cocitation ties with papers that report the discovery of an antigen associated with type-B viral hepatitis. Although these papers first appeared in 1966, intensive research on the implications of the discovery was not reported until after

1969. Unlike the reverse-transcriptase cluster, the Australia-antigen cluster remained an independent cluster from 1970 through 1973. Therefore, for analysis, we chose all documents included in the cluster in any of the four years—a total of 82.

For each cluster, our next step was to list all first authors of documents and any subsequent authors who coauthored more than one paper. Using this specification, we obtained the names of 105 scientists for the reverse-transcriptase cluster and 65 scientists for the Australia-antigen cluster.

For each scientist, we obtained sociometric data from two sources. The first was a questionnaire mailed to the individuals in the groups asking each to report on nine types of sociometric tie with each of the other scientists on the list for his or her group. The nine ties included three measures of awareness ("Have you ever heard of X?"; "Do you follow the work of X?"; "Do you know X well?"), two indicators of teacher-student relations ("Are you a teacher of X?"; "Are you a student of X?") and four measures of collegueship ("Are you a colleague at the same institution with X?"; "Have you ever been a co-worker with X?"; "Are you presently a co-worker with X?"; "Have you ever been a coauthor with X?"). We obtained completed questionnaires from 82% of the authors in the Australia-antigen cluster and 86% of the authors in the reverse-transcriptase cluster. The questionnaires were mailed and collected during May-July, 1975. The second source of sociometric data was the *SCI*. From it we obtained for each year between 1967 and 1973, each author's citations of any document by any of the other authors in the list for his or her group.

Since we wanted to determine the extent to which social patterns among scientists reflect features of their intellectual products (see Griffith and Mullins, 1972), we searched for published reviews of the research reported in the papers and interviewed selected authors of documents in the two lists. This information was gathered between May, 1975, and December, 1975.

¹ Small (1977) reported a case study of a cocitation cluster concerned with collagen research in which specialists were asked to list (1) the most important papers in its recent history and (2) the leading investigators in collagen research. He found that (1) usually the more higher-cocited papers were more often mentioned by his respondents and (2) the researchers frequently named as leading investigators were more likely than other investigators to have written highly cocited papers. This result is consistent with Chubin's characterization of cocitation clusters as highly visible slices of the scientific literature, but it does not show whether the authors of higher-cocited papers form a coherent social group.

RESULTS

The Cognitive Developments

Both the published reviews and the interviews revealed that the documents in both clusters did, in fact, reflect important intellectual developments and were not merely highly visible slices of scientific literature. The reviews and the interviews also showed important differences between the two areas. As we noted above, the original discovery of Australia antigen was reported in 1966. Immediately afterward, ambiguities about the source and nature of the antigen attracted the discoverers' attention. For some time, researchers believed that a new mechanism of disease causation might be involved (Maugh [1975] discussed developments in this research through 1975). Because of these difficulties, the development of a vaccine for hepatitis B was delayed until 1975. Nevertheless, from 1966 on, research was continuous (becoming more intense after 1968), the original discoverers continued to do research on the topic.

Reverse-transcriptase research has followed a different pattern (Culliton [1971] reviewed research up to 1971). In the middle 1960s, investigators had suggested the possibility that genetic information could be transferred from RNA to DNA, but convincing evidence of the transfer was not presented until 1970. This evidence was presented simultaneously by two groups working independently on somewhat different materials and the investigators involved received Nobel Prizes for the research. After a flurry of activity devoted to specifying more precisely the exact mechanisms that transferred information from RNA to DNA, the researchers moved on to study related by somewhat different topics in oncology and viral genetics. Thus, unlike the research on Australia antigen, which has been fairly continuous since the middle 1960s, work on reverse transcriptase has been declining since the early 1970s.

We now consider whether the sociometric data show that the authors in each group have relationships that would be expected of either currently or recently

existing scientific specialty groups.² We focus on three separate but interrelated questions: To what extent do the authors in each group show high levels of mutual awareness and relatively dense social contacts?; To what extent do the two groups of authors exhibit social structures consistent with previous descriptions of social structure in scientific specialties?; To what extent do the two groups show patterns of growth and change consistent with our knowledge about their patterns of cognitive development?

Awareness and Social Contact

Since there are no previously established levels of awareness, teacher-student ties and collegial ties that we can use as standards for deciding whether a given group of scientists is a scientific specialty, we compare our findings with those from previously published case studies. Table 1 shows the results for the three measures of awareness. The figures are the proportions of the total possible links ($N^2 - N$) that respondents reported for each of the three measures. Thus, .74 for "ever heard of" among reverse transcriptase researchers shows that they formed nearly three-fourths of the 10,920 links that were possible among the 105 respondents from this group.³ Breiger's (1976) results, from reanalysis of data on another biomedical specialty, are not strictly comparable to ours because he reported responses to a question about "unawareness" rather than "ever heard of"; also, he gave the proportion of "mutual

² Given the lack of agreement on a term to characterize the social entity we are studying, we use the term "specialty" to mean typically small and informally organized groups of researchers who carry out work on a given question or topic. The groups could also be called "invisible colleges" (Price, 1963) or "research areas" (Whitley, 1974), but "specialty" is the term most often used by previous researchers who have studied these groups.

³ In the analysis, we have included those who did not return questionnaires because they were recipients of "choices" from the respondents. Obviously, since the nonrespondents reported no ties with the respondents, our results necessarily underestimate the true densities of ties for our groups. Nevertheless (see below), our densities exceed those reported in previous studies, even those from data that also exclude nonrespondents (Breiger, 1976).

contacts" rather than the proportion who knew each other well. Since "know well" probably captures a higher level of awareness than is indexed by "mutual contact," the results show that levels of awareness in our two groups are higher than the levels among researchers studying the neural control of food and water intake.

Crane (1972) described student-teacher and colleagueship ties in two specialties. One, in mathematics, concentrated on the theory of finite groups; the other, in rural sociology, concentrated on the diffusion of agricultural innovations. She computed "group connectivity scores" that included both direct ties between specialty members (e.g., the kinds of tie reported in Table 1) and indirect ties for all numbers of steps (Crane [1972:41-4] describes this technique). To obtain comparable figures for our two groups of scientists, we computed connectivity scores for four ties that

are similar to hers. Table 2 shows three kinds of information for each tie: density of direct contacts (as in Table 1) for our two groups, and connectivity scores reported by Crane for her two specialties.

The first two ties, current collaboration and published collaboration, are measured in comparable ways in our study and Crane's. In both cases, our scores are substantially higher than hers. Indeed, in our two groups, direct ties for these two relationships are as dense as all ties, both direct and indirect, in Crane's two specialties. In our two groups, only the connectivity scores for "teacher of" are of sizes comparable to those for Crane's specialties. On the other three relationships, the authors of our two clusters of papers exhibit denser patterns of contact than do the members of other scientific specialties that have been studied. This result supports the claim that highly co-

cited papers are produced by members of scientific specialties.

Social Structure

Scientific specialties typically display a social structure that, for many social relationships, can be described as a "center-periphery" pattern (Breiger, 1976:128-9). The center is a subset of members who are recognized by others as being central to the specialty. These scientists are more productive than their peers, and among them are those who made the original discoveries that are the intellectual basis of research in the specialty. These scientists usually have central locations in the specialty's pattern of information flow and usually are important to its organizational development also (Mullins, 1972; 1975; Crane, 1972: 49-56). In contrast, peripheral members are less visible to both the core and each other. They are usually linked to only one or a few members of the central group. In addition to central and peripheral members, some specialties include outsiders who, although they have published research on the specialty's topic, show little awareness of core and peripheral members who, in turn, show little awareness of the outsiders. These scientists may show high levels of productivity and eminence in the larger discipline, but their primary research orientations apparently are outside the specialties studied (Breiger, 1976:131-2; Cole and Zuckerman, 1975). To determine whether these general structural features were present in our groups of authors, we did a block-model analysis of each group using the nine sociometric ties reported in the

questionnaires. Block modeling (White et al., 1976) partitions the members of a population into mutually exclusive and exhaustive subsets (blocks). For all sociometric ties in the analysis, the members of each block have equivalent relations with members of other blocks. Thus, for the ties in a given study, the members of a block are structurally equivalent (White et al., 1976:737-40).

We partitioned the two groups of authors by using a variation of the CONCOR hierarchical clustering algorithm (Breiger et al., 1975).⁴ The algorithm was applied to a sociomatrix containing the nine types of tie listed above. In both instances, a four-block partition provided a detailed picture of structure without excessive loss of cases in the blocks. Figure 1 shows the successive partitions of the two groups. The roman numerals are labels for the blocks.

Table 3 shows the patterns for three levels of awareness, presented as 4×4 matrices in which each matrix is a reduced form of the original, individual-level sociometric matrix. For example, for the Australia-antigen (AA) authors, we began with a 65×65 matrix showing ties for "ever heard of." We permuted the matrix to sort the authors into the four AA blocks shown in Figure 1. Thus, the 4×4 AA matrix for "ever heard of" (shown in Table 3) represents the structure of this type of awareness for the four blocks of structurally equivalent authors. The

Figure 1. Successive Partitions of Authors

⁴ CONCOR is an inefficient technique for extracting information from sociomatrices (Schwartz, 1977), but is adequate for detecting the general structural characteristics of interest in this article.

IV	.12	.03	.04	.04	IV	.08	.08	.02	.02

entries in the matrix are the densities of contact within and between the blocks. Specifically, the entry in cell i, j of this matrix is the number of times members of block i report that they have ever heard of an author in block j divided by the number of such reports that were possible ($n_i \cdot n_j$ when $i \neq j$, $n_i^2 - n_i$ when $i = j$).

If a center-periphery structure exists among the blocks, it will appear as strong ties within one or more core blocks, strong ties between a center block and its "follower" blocks (but not between these follower blocks themselves) and, perhaps, weak or nonexistent ties between some blocks and both center and follower blocks. With proper arrangement of the blocks, this kind of structure would be reflected in high-density cells at one of the two main-diagonal corners of a matrix, with increasingly low densities becoming prominent as one moves toward the opposite, main-diagonal corner.

The results in Table 3 generally confirm the hypothesis that the two groups of authors conform to the center-periphery structure. The types of awareness shown in Table 3 range from the weak "ever heard of" (for which overall density is high) to the strong "know well" (for which overall density is low) and, as expected within a given type of awareness,

the densities decline fairly uniformly from the upper-left to the lower-right corners of the matrixes. In all but three cases,⁵ the exceptions to the general pattern are small enough to be easily attributed to sampling variation and unreliability of measurement. For each group, members of block I are both more visible to members of the other blocks and more aware of those members than they are of themselves. This pattern is repeated if we successively remove blocks I and II from consideration. Thus, in each specialty, the members of block I constitute the center of the group, and the members of blocks II through IV are increasingly peripheral. Unlike Breiger's hunger and thirst specialty, however, there appears to be no outsider block in either of the two groups.

Table 4 shows the densities for five types of social contact. In general, the results are consistent with those in Table 3. For example, in both RT and AA, the members of block I are more likely than members of any other block to have

⁵ For Australia antigen, block III shows unexpectedly high intrablock awareness for "ever heard of" and "know well." For the same two relationships, members of block II show relatively low awareness of members of blocks III and IV. For reverse transcriptase, relatively few of the authors in block II have ever heard of authors in blocks III and IV.

taught members of other blocks. The other four types of contact repeat the center-periphery pattern. Overall, these results are consistent with previous theories about teacher-student relationship patterns of information flow in scientific specialties (Mullins, 1975). The major exceptions to the center-periphery pattern in Table 4 apparently explain some of the deviations from this pattern in Table 3 (see footnote 5). In particular, members of AA block III show considerable contact with each other, a finding that is consistent with the AA block III's high density of "know well" ties (Table 3). In contrast, AA block II shows surprisingly little contact with blocks III and IV and this finding may account for the relative lack of ties for "ever heard of" and "know well" be-

tween AA block II and AA blocks III and IV (Table 3).

Thus far, our inferences about center and peripheral groups have been based solely on the sociometric patterns of awareness and contact. By themselves, the sociometric results do not necessarily prove that these two groups of authors exhibit the social structure of a scientific specialty. Therefore, we will now show that the blocks identified above as central blocks (I in AA and RT) do indeed consist of the highly productive and eminent scientists specified in our earlier discussion of a scientific specialty's typical social structure.

Preliminary evidence is the fact that in each group, scientists in block I wrote the original discovery papers. More complete

evidence is presented in Table 5, which shows the block-specific means for six variables that reflect status differentials among the blocks in each group. The results are consistent with the patterns of awareness and contact shown above. For example, RT's block I authors had the oldest Ph.D. degrees (a measure of professional experience), and they exceed the members of the other blocks on the five other measures of status (which indicate performance). RT's blocks II through IV show no consistent pattern on age of degree, but they do show a consistent hierarchical ordering on the five performance measures. The AA authors show no clear pattern for professional experience and papers published, but they do show the expected hierarchy for the more recent performance measures (funding received and 1970 and 1973 citations). Thus, for both groups the data on status generally confirm the inferences drawn from the block models.

Patterns of Change

Thus far, our analysis has been based on cross-sectional sociometric data. The data are fully consistent with the hypothesis that both groups of authors of highly cocited documents constitute scientific specialties. Now we analyze longitudinal data on patterns of citations to all documents, including the highly cocited papers, among the authors of each cluster.

In this analysis, we emphasize the fit between changes over time in patterns of citation and what we know about the cognitive development of the two specialties.

Table 6 shows citation patterns for both groups for four periods during the years from 1967 to 1973. These four periods were determined by examining the density levels and patterns for all years and then combining consecutive years that showed strong similarity. Two results for AA are especially noteworthy. First, there are substantial changes in overall density. Beginning with fairly low densities during 1967 and 1968, there were substantial increases in 1969 and 1970. The high densities in 1970 were maintained until 1973, when they began declining. Second, there are changes in the pattern of citation over the period, and these changes occur precisely when the density changes. During the earliest period, block I was cited slightly more than any other block, but all blocks show intrablock densities that are higher than any of the interblock densities. In 1969 a center-periphery pattern began to emerge. It was quite strong during the period from 1970 to 1972 but the pattern began to weaken in 1973.

These two changes conform fairly closely to the intellectual development of the specialty described earlier. Intensive research in the area did not develop until the late 1960s and early 1970s. When it did develop, the authors who had made the

original discoveries in 1966 constituted a clearly bounded central group. This group maintained its position after 1972 but, as work in the area became less intense, citation densities among the group declined.

Similar results are shown for RT authors. The citation densities were relatively low from 1967 to 1969, and then increased to a peak in 1971, the year following the publication of the discovery papers. Then a decline in densities occurred during 1972 and 1973. Once again, the earliest period shows a pattern wherein block I receives more citations than the other blocks, but intrablock densities are generally higher than interblock densities. This pattern changes to a center-periphery pattern as densities increase, but the original pattern reemerges when the densities decline (1972-1973). The chief difference between the two groups is the more sustained period during which Australia-antigen authors main-

tained high citation densities and a center-periphery pattern.

In general, the longitudinal results for the two groups of authors correspond fairly closely to the cognitive development. Both groups show the same general changes in densities and patterns, and these changes occur at the expected points in time. Furthermore, the chief difference between the two groups is consistent with the fact that research on reverse transcriptase occurred during a shorter period of time than research on Australia antigen.⁶

⁶ Given the lack of methods for testing statistical hypotheses about changes in the densities and patterns of ties in sociometrics (Granovetter, 1976), we cannot determine whether the results shown in Table 6 can be reasonably attributed to random sampling and measurement error. Given the consistency of our social structural results with known intellectual characteristics of the two groups, however, we doubt that either sampling or measurement error produced the social structural results.

For both groups, the decline in citation densities and the weakening of the center-periphery pattern during the most recent period cannot be attributed to a decline in the scientific activity of their members. Data on publication (not presented here) show that the scientists in our study have continued to publish at the rates they did during the two groups' peak years. Furthermore, although the members of each group now cite each other less often than during the peak years, they have received increasing numbers of citations from the scientific community as a whole. These results suggest that, with the passage of time, the scientists in each group have turned their attention to other research topics. This kind of shift among the central scientists in a specialty has been suggested as the modal pattern of specialty decline (Mullins, 1975; Mulkay, 1975). In sum, the longitudinal citation data for both groups of authors further corroborate the conclusion that the two clusters of highly cocited documents are indeed the products of scientific specialty groups.

CONCLUSIONS

In this paper, we have examined various features of the social structure exhibited by the authors of two clusters of highly cocited papers. Both groups are dense social networks, and both show patterns of social ties that are consistent with previous accounts of the social structure of scientific specialties. In addition, changes over time in the flow of citations among the authors in each group closely match the cognitive development of the two research areas. Finally, differences between the two groups, such as the different times of peak activity and the difference in citation densities during these periods, also match closely the different cognitive development of the two areas.

On the basis of these results, we conclude that the highly cocited papers were produced by scientists who were, when the papers were written, members of scientific specialties. The findings strongly indicate that cocitation analysis can identify scientific specialties and thus be a

promising tool for the comparative analysis of specialty growth and development. Two directions of inquiry seem promising. First, researchers should do more detailed analyses of the social structures of groups such as those discussed in this paper. The consistency in the relationships among blocks across different types of social contact suggests the existence of coherent role relationships, and the algebra of these relationships (Boorman and White, 1976) needs explication. Second, the kinds of research group identified by cocitation analysis are not equivalent to some of the entities discussed in previous work on scientific specialties. The two groups examined in this paper, for example, fit the models of neither the "revolutionary" nor the "elite" specialty (Mullins, 1973:299-300). We believe that analyses of additional research groups detected by cocitation analysis will yield information about the variety of structures currently encompassed under the term "specialty" and the dynamic processes of specialty growth, transformation and decline.

THE REALISM OF EDUCATIONAL AMBITIONS IN ENGLAND AND THE UNITED STATES*

ALAN C. KERCKHOFF

Duke University

American Sociological Review 1977, Vol. 42 (August):563-571

Differing characteristics of the educational systems in England and the U.S. lead to the hypothesis that educational expectations should become "realistic" earlier in adolescence in England than in the U.S. Several definitions of realistic are used in the analysis of data obtained from thirteen-year-old boys in both countries. The hypothesis is generally supported, but the English boys are found to overestimate the significance of ability in the process of educational attainment. This overestimate is also found for older English boys, while older American boys report the most realistic expectations of any of the samples studied. These findings are interpreted as indicating different effects of the institutional characteristics of the two educational systems.

Discussions of the aspirations of adolescents note that the levels of expected (or hoped for) attainment reported by young people are often quite unrealistic. This usually means that there are many more respondents who aspire to high levels of attainment than can possibly be expected to reach them.¹ The difference between ambition and probable attainment evidently becomes smaller as the respondents get older, however, and by the

time American students are in twelfth grade, there is a rather close correspondence between their educational expectations and their probable attainments (Kerckhoff, 1974a).²

The unrealistic ambitions appear to reflect ignorance of the association between antecedents and attainments. Thus, if ambitions become increasingly more realistic as adolescents near maturity, there must be some process through which this greater realism is brought about. There is evidently a growing appreciation both of the probabilities of reaching various levels of attainment and of one's own potential in relation to this set of probabilities. Our current understanding of the process of social stratification leads us to believe that, initially, the two most important predictors of ultimate level of attainment are one's social origins in the stratification system and one's academically relevant ability (Sewell and Hauser, 1972; Haller and Portes, 1973).

Information about the factors associated with various levels of attainment and about one's own position in the distribution of these factors undoubtedly comes from a variety of sources. Family, friends, the mass media and the school all contrib-

* A revision of a paper presented at the Seminar on Mobility and Social Stratification, sponsored by the International Sociological Association Research Committee on Social Stratification, Jerusalem, April, 1976. The data sets used in this study originally were assembled for my analysis under grants from the National Science Foundation and the Office of Education. The I.E.A. data were made available through the assistance of Richard M. Wolf of Columbia University, and the Peaker data were made available by Douglas Pidgeon, then of the National Foundation for Educational Research in England and Wales. I gratefully acknowledge their assistance. I also am indebted to Alan Parrow and Sharon Poss for computational assistance and to Frank Bean, Richard T. Campbell, James S. House and an anonymous reviewer for critical reviews of earlier drafts of the article.

¹ For instance, in Turner's (1964) study of Los Angeles high school seniors, over half of the boys expected to attain professional or semi-professional occupations, and two-thirds expected to obtain some college education. In light of their backgrounds, which were generally similar to those of the U.S. population, such expectations almost certainly could not be realized.

² The same source suggests that this is much less true for occupational expectations, twelfth graders being almost as unrealistic as sixth graders.

ute to this understanding. The school is especially important for obtaining an assessment of one's own relative position, since the school uses objective assessment methods and deals with nearly the full range of individual abilities. In all modern societies, the educational systems not only teach the child but also report on how well he/she is doing in relation to others at the same level of development. Schools also (at least implicitly) inform the individual of the long-range significance of different levels of academic performance.

School systems differ, however, in the kind and amount of feedback they provide to their students. Some provide much more explicit reports of the students' levels of performance and, especially, of the long-range significance of these levels. The more explicit the feedback, the more realistic one would expect the child's view of the future to be. For instance, school systems in societies having what Turner (1960) has called "contest" and "sponsored" mobility processes would be expected to differ in the explicitness of feedback and, thus, we would expect adolescent ambitions to differ in their degree of realism. In a system of *contest* mobility,

elite status is the prize in an open contest and is taken by the aspirants' own efforts. . . . Under *sponsored* mobility elite recruits are chosen by the established elite or their agents, and elite status is *given* on the basis of some criterion of supposed merit and cannot be *taken* by any amount of effort or strategy. (Turner, 1960:856)

Turner uses England and the United States as examples of sponsored and contest mobility systems, respectively. In the traditional English system, a decision is made when the child is eleven or twelve years old regarding the type of secondary school he/she will attend. The major differentiation is between two rather different types of schools. They are the grammar school and the secondary modern school, the former providing a much more demanding and academically-oriented curriculum intended to prepare students for post-secondary education. The selection process depends very heavily on the children's performance on achievement tests and the expert judg-

ment of educators.³ This division thus separates the students into two groupings having significantly different long-range possibilities. In contrast, the American system of contest mobility provides somewhat more opportunity for adolescents to change course throughout secondary school and encourages the belief that such change is possible.

Information about one's performance and potential which is received from the school system thus would be expected to have very different meaning in these two cases. In the English case, a clear-cut and presumably irrevocable message, which defines the future within rather narrow limits, is received at an early age. Turner (1960:859) interprets the English system: "The earlier that selection of elite recruits is made, the sooner others can be taught to accept their inferiority and to make 'realistic' rather than phantasy plans." In the American case, on the other hand, feedback is likely to include expressions of hope and encouragement for better performances in the future. This hope and encouragement provide a basis for unrealistic expectations and they reduce the likelihood that children will use the most relevant bases for estimating their potential for future attainment.⁴

The present paper is part of a broader investigation of educational expectations and attainment in England and the U.S. which takes this differentiation between

³ The English school system has been changing significantly during the past decade. In particular, there is much less dependence on examinations (the so-called 11+) as the basis of secondary school assignment, and a new form of school, the comprehensive school, has been introduced. The latter includes both types of students, though often in thoroughly segregated tracks. These changes had hardly begun, however, at the time the data analyzed here were collected. Thus, the dual secondary school system, in which assignment was heavily influenced by ability and performance measures, was predominant. There were, of course, several other kinds of schools besides the grammar and secondary modern schools, even in the 1960s, but the great majority of students attended one of these two types, and the others can rather easily be classified into the dichotomy formed by these two. Finally, the school-leaving age has been raised from fifteen to sixteen since the data used in this analysis were collected.

⁴ Yuchtman (Yaar) and Samuel (1975) use a similar conceptualization of the differences in the systems when comparing Israel and the U.S.

the educational systems in the two countries as its point of departure. The primary concern here is to examine the general hypothesis that educational expectations become realistic much earlier in England (under a sponsored mobility system) than in the U.S. (under a contest mobility system). In making this comparison, three forms of analysis involving three levels of specification of the general hypothesis will be employed. First, the average educational expectations of samples of English and American adolescents will be compared with the average attainments of young adults in the two societies to see if there is a general tendency for the American adolescents, more than the English, to have unrealistically high expectations. Second, a predicted level of attainment will be estimated for each individual in both samples, based on a prediction equation derived from earlier research, and the individuals' own expectations then will be compared with these predictions. The hypothesis would call for a greater similarity between these predictions and the individual's own expected attainments in England than in the U.S.

A third form of analysis will be used to assess the degree to which adolescents, in reporting their educational expectations, weight the relevant factors in ways that are similar to their weights in the determination of actual attainments. Specifically, we will see if the relative weights of social origins and ability are the same when the subjects' expectations are regressed on these variables as they are when the attainments of young adults are regressed on them. This is the most refined way we have of assessing the degree of realism of the boys' expectations. If the English system of sponsorship functions more effectively than the American contest system to inform students about the process of attainment, we would anticipate that the two equations would be more nearly the same in England. Since assignment to one of the two types of secondary schools is presumably an important source of information about one's future in England, this third type of analysis also will examine the effect of secondary school assignment on expectations in England.

Although there is adequate reason to

hypothesize that these English-American differences will be found at some point in the life of an adolescent, it will be important to take the age of the subjects into account. This is true for two reasons. First, it is not necessary to infer that in a system of contest mobility young people *never* obtain a realistic view of their probable attainments; it is only necessary to infer that they are slower to do so than young people in a system of early sponsorship. Thus, our guiding hypothesis is that English adolescents will become more realistic *earlier*. Second, the differences in the educational systems make it difficult to equate young people solely on the basis of age. A large proportion of English adolescents leave school before age sixteen while most American adolescents are still in school at seventeen. Thus, it will be necessary to consider not only chronological age when comparing adolescents in the two countries but also to consider how close they are to the average school-leaving age. Both reference points will be used in the analysis.

Method

In 1964, the Council of the International Project for the Evaluation of Educational Achievement (I.E.A.) conducted a study of mathematics performance in twelve countries, including England and the U.S. (see Husén, 1967, for a discussion of the overall study). National samples were drawn from those students who were thirteen years old—most of them were presumably in the eighth grade in the U.S. and the second form in England. Although both boys and girls were included in the samples, only data from the boys are used in the present analysis. There are 2,489 American and 1,231 English boys in the samples studied.

The primary analyses will be conducted with these samples, but two other data sets will also be analyzed. The I.E.A. thirteen-year-olds are at different points in the normal pattern of secondary school education in the two countries, the English boys being closer than the American to the point at which most students leave school. Thus, the two other data sets are from samples of boys who are at

different ages but who are at the same general place in the educational system, namely, at the point just prior to when most students leave school. One data set is from a sample of fourth form (roughly fifteen-year-old) English boys studied by Peaker (1971). This is a subsample of 382 boys taken from a larger national sample. The other is from a sample of American white male high school seniors studied by Kerckhoff (1974a). The 956 boys in the sample are from Fort Wayne, Indiana. Although the variables were not measured in the same way in these two studies, nor in the same way as in the I.E.A. study, all data sets contain measures of the same variables. The measurement methods are outlined in Table 1, and the details are reported in the research reports cited.

The analysis will be presented in four stages. First, the average number of years of additional education expected by the I.E.A. thirteen-year-olds will be compared with experts' estimates reported at the same time. Second, a regression equation found to be effective in predicting the actual attainments of young adult males in the two countries will be used to generate

individual attainment predictions, and these will be compared with the individual expectations reported by the boys in the I.E.A. samples. Third, the regression weights in the attainment prediction will be compared with the weights found using the same independent variables to explain the I.E.A. boys' expectations. All three of these analyses will be used to test the hypothesis that the English expectations will be closer to the predicted outcomes than will the American expectations. Finally, an analysis which parallels the third will be conducted using the fifteen-year-old English and the seventeen-year-old American subjects. This analysis will be used to see if the inter-nation comparison is the same when the samples are equated on the time away from the average school-leaving age rather than being equated on chronological age.

Results

The simplest definition of realism is based on a comparison between a group's average level of expected attainment and the experts' best estimates of predicted

Table 1. Measures of Variables Used in the Analysis

Variable	Data Set		
	I.E.A. Thirteen-Year-Olds	English Fourth Form	U.S. Seniors
Father's Occupation	Five categories ranging from "Professionals and Managers of Large and Medium-Sized Organizations" to "Unskilled Workers." Coded 5-1	Six categories ranging from "Professional" to "Unskilled Manual." Coded 6-1	Duncan SEI Scale scores
Father's Education	Number of years of education received	Age at which he left school	Nine categories ranging from "Eighth Grade or Less" to "Graduate or Professional School." Coded 1-9
Ability	"Total Mathematics Test Score." Constructed by summing several sub-test scores	"Total Test Score." Composed of both verbal and quantitative sub-tests	Lorge-Thorndike I.Q. Test Score
Educational Expectations	Number of years of additional full-time education expected	Age to which they expected to stay in school	Amount of education expected. Six precoded answers ranging from "Quit High School before Graduating" to "Graduate or Professional School." Coded 1-6

attainment. Estimates of the probable average educational attainment of boys who were thirteen years old in 1964 were obtained from Robbins (1963) for the English and from Simon and Grant (1967) for the American samples.⁵ These sources indicated that American boys of thirteen would probably obtain 5.6 additional years of education on the average, and English boys would probably obtain 3.5 additional years on the average. The American boys in the I.E.A. sample said they expected an average of 7.4 years of additional education, and the English boys said they expected an average of 3.9 additional years. This is, at best, only a crude index of the boys' realism, but there is little doubt that, according to this index, the English boys were more realistic than the American boys. The American ambitions were clearly too high by this definition, but the English ambitions were only slightly high.

The prediction equation used to derive individual predicted attainments for the I.E.A. boys was taken from Kerckhoff (1974b). In that study, it was shown that a path analysis using social origins and ability as predictors of the actual educational attainments of young males produced surprisingly similar results in the two countries. That analysis suggests that a single set of standardized regression coefficients can be used to predict educational attainment in the two countries,

⁵ Both of these sources provides tables in which educational attainments are estimated for past and future years. In Simon and Grant (1967:7), Table 8 reports "estimated retention rates, 5th grade through college entrance" for the beginning years (when students were in 5th grade) from 1924-1925 through 1959-1960. Figure 2 (1967:8) reports "estimated retention rates, fifth grade through college graduation" for the beginning year of 1959-1960. The combination of these two sources makes a fairly exact estimate possible, though the estimate does not control for sex. In Robbins (1963:103), Table 3 gives "percentage of each age group [ages 15 through 19 and over] at school in January" for England and Wales, by sex, 1950-1985. Table 31 (1963:148) reports "initial entrants to higher education as percentage of the age group," by sex, 1954-1962. Table 34 (1963:151) gives similar information for 1955-1985. These latter two tables, together with data in Section 8 on "length of courses," make estimates of post-secondary school attainments possible. In both sources, there are other statistics cited against which the estimates used in the present analysis could be checked.

using social origins and ability as predictors. The equation derived from that source and used in the present analysis is:

$$\hat{Y} = \sum_{i=1}^k [\beta_{ij}(X_{ij} - \bar{X}_{ij})/S_{ij}]S_{yj} + \bar{Y}_j$$

where β is the standardized regression coefficient applicable to both countries, i refers to the particular independent variable (father's occupation or education or son's ability), j refers to the country (England or the U.S.), S_{yj} is the standard deviation of the particular variable for the country, and \bar{Y}_j is the predicted mean additional years of education for the country. By using the means and standard deviations appropriate to the particular country, it is possible to transform the original equation, based on standardized coefficients, into an equation based on metric coefficients appropriate to the particular measures used in this study.⁶ The \bar{Y} scores produced in this way can be rounded to the nearest whole year and then used as an individual's predicted attainment level. Throughout the discussion, the boys' estimates of their future attainments will be referred to as "expected attainment" while the rounded scores produced in this way will be referred to as "predicted attainment."

When the predicted attainment scores are cross-tabulated with the expected attainment scores, the two scores are identical for 33.4% of the English and 18.8% of the American boys; they are either the same or within one year of each other for 74.6% of the English and 52.2% of the American boys.⁷ Thus, again, by this more refined definition, we find the English I.E.A. boys' expectations to be more realistic than those of the American boys.

⁶ The standardized coefficients used in the analysis conducted here are those reported by Kerckhoff (1974b: Table 3) as "Duncan (uncorrected)" for the American equation and "Douglas (a)" for the English equation. An analysis that is fully parallel to the one presented here was conducted reversing the standardized coefficients but leaving the rest of the computation the same. It produced somewhat different results, but the overall pattern was the same.

⁷ The gamma, computed for the cross-tabulation of these two sets of scores, is .709 for the English and .338 for the American sample.

Yet, the analysis presented thus far does not demonstrate that the closer fit between predicted and expected levels of attainment in England result from the English boys' having based their expectations on the same antecedents which help explain actual attainments. Since the best prediction equation available uses social origin and ability as the bases of prediction, a wholly realistic group of boys (by this definition) would report expectations that are associated with these antecedents the same way as attainments are.

Table 2 provides a number of bases for comparing the antecedents of educational attainment (the source of our prediction equation) in the two countries with the antecedents of the boys' expectations. The "Path Coefficients" are taken from a path analysis in which expectations (or attainments) are regressed on ability and SES. "Gross Effects" refers to the proportion of the variance in expectations (or attainments) which can be explained by ability or SES alone. It is the square of the correlation between ability and expectations (or attainments) and the square of the multiple correlation of father's occupation and father's education with expectations (or attainments), respectively. "Unique Effects" refers to the additional variance of expectations (or attainments) explained by ability or SES when added to the gross effects already attributable to the other source. R^2 is the total variance explained by the combination of ability and SES. (It is the sum of the ability gross effects and SES unique effects as well as the sum of the SES gross effects and ability unique effects.) For the moment,

only the first two rows of Table 2 will be discussed.

Not surprisingly, given the earlier analysis, the R^2 of expectations with social origin ability is much larger in England than in the U.S. Also, both the gross and the unique effects of both ability and social origin are stronger in England.⁸ All of these findings are consistent with the general hypothesis and with the earlier findings. English boys report educational expectations which show strong effects of social origin and ability. Also, consistent with the presumed basis of sponsorship in the English system, ability is a stronger source of explanation of expectations in England than social origin is, while the two effects are nearer to being equal (though weak) in the U.S. All of this is consistent with the view that the sponsorship system provides relatively young boys a clear indication of their probable attainments, while a system of contest mobility leaves the outcome more ambiguous.

When these results are compared with those based on a parallel analysis of educational attainment (reported in the last row of Table 2), however, a somewhat different impression is gained. On most of the measures, the results from the analysis of educational attainment fall between the two sets of results for educational expectations. Clearly, if we use the effects of

⁸ It should be noted that some of the differences between metric coefficients are not the same as the differences between the path coefficients, due to differences in variance of some variables in England and the U.S. The overall contrast is still large and in the same direction, however.

Table 2. Antecedents of Educational Expectations and Attainments in England and the United States

Dependent Variable and Data Set	Path Coefficients			Gross Effects of		Unique Effects of		R ²
	FaOcc	FaEd	Ability	SES	Ability	SES	Ability	
Expectations								
English 13-year-olds	.187	.179	.456	.269	.351	.088	.170	.439
U.S. 13-year-olds	.051	.261	.192	.123	.081	.075	.033	.156
English 4th Form	.109	.136	.538	.133	.358	.041	.265	.399
U.S. 12th Grade	.165	.246	.367	.227	.225	.126	.124	.351
Attainments in England and U.S.*	.233	.204	.381	.209	.234	.134	.159	.368

* These effects are based on simple averages of the effects reported in Kerckhoff (1974b: Table 3) for the "Duncan (uncorrected)" and "Douglas (a)" analyses for the U.S. and England, respectively.

the antecedent variables on attainments as our definition of realism, the English boys are almost as unrealistic as the American boys, only in the opposite direction. They tend especially to *overestimate* the importance of ability in educational attainment.

A strong emphasis on the importance of ability, even an excessively strong emphasis on ability, might be anticipated in a country like England whose educational system is organized to sponsor the development of promising young people. Just two years prior to the time these data were collected, these English boys experienced the all-important division into two types of secondary education, a division that is presumably based largely on measures of academic achievement and promise. Those selected for grammar school realistically should expect higher levels of educational attainment than those attending secondary modern schools, and the type of school attended is certain to be associated with ability level. If the direct effect of secondary school assignment is the reason for the strong emphasis on ability, however, two other outcomes also should be observable. First, we should find a high correlation between ability and type of school attended. Second, when school type is introduced into an analysis of the antecedents of educational expectations, it should sharply reduce the effect of ability on expectations.

These outcomes are found, but they are weaker than might have been expected. The correlation of ability and school type is .49. Given the presumed bases of the secondary school selection process, this is not very high, but it is consistent with others' findings.⁹ When school type is used as a fourth antecedent variable (together with son's ability and father's occupation and education) in the explanation of educational expectations, it does reduce the direct effect of ability on expectations but by less than one-fifth. (Reductions in the two SES paths are inconsequential.) The path coefficient for ability in such an analysis is .379, compared with the .456 reported in Table 2. By comparison, the path coefficient for school type is

.174. Here again, the effect is smaller than would be expected if secondary school assignment were the major source of influence on English educational expectations. Even when the specific effect of school type is partialled out, the remaining direct effect of ability is still stronger in England than in the U.S. The English boys are sensitive to the significance of ability in educational attainment, over and above its direct relevance for secondary school assignment. It is not clear why this is so, but it might be due to the use of "tracks" within each type of school or simply to a heightened salience of ability in all school activities.

All of these findings are based on data from thirteen-year-olds in the two countries. One might legitimately ask whether the age of the subject is an important factor in determining the results reported. Are the differences reported found only among young adolescents or do they persist throughout the pre-adult period? Do American boys continue to be less realistic and do English boys continue to overestimate the importance of ability? Can the differences noted be attributed in part to the fact that the English boys were, on the average, closer than the Americans to the point at which most of them leave school? Similarly, are the English results affected by the English boys' recent experience with the secondary school selection process, a process that heightened their awareness of the importance of ability?

Although such questions cannot be answered with certainty, additional analyses using the two older samples described earlier help to put the previous findings in perspective. It will be recalled that the older English boys were in the fourth form and the older American boys were in their senior year in high school. Therefore, they were at or nearing the age (fifteen in England, seventeen in the U.S.) at which most boys leave school. Their views of their probable educational attainment should be as realistic as we could hope to find among adolescents in the two countries.

Analyses parallel to those reported above were conducted with these data, and the results are reported in rows three and four of Table 2. A comparison of these

⁹ Douglas (1964) examines this relationship in detail.

results with those for the thirteen-year-olds in rows one and two indicates the following: (1) The English fourth-form data produce results that are very similar to the English thirteen-year-old findings. If anything, the relative effect of ability on expectations is even stronger among these older boys. (2) The American seniors' data produce results that are quite different from those for the American thirteen-year-olds. Social origins and ability both contribute more to an explanation of expectations among these older boys than among the younger American boys. (3) Of the four analyses of expectations, the one which most closely approximates the analysis of attainments (reported in the last row of Table 2) is from the American high school seniors.

The data used in this further analysis are certainly not ideal for our purposes, but they do provide both support for the initial findings and a basis for interpreting those findings. The strong effect of ability on educational expectations in England is found among the older as well as the younger boys. There is thus no indication that the young English boys' overemphasis on the importance of ability is a temporary effect. We also find among these older boys, as we did among the younger ones, that the strong effect of ability is not wholly dependent on secondary school assignment. Secondary school assignment is only modestly correlated with ability in both cases (.48 compared with .49 among the younger boys). And when type of secondary school is used in the analysis, it again reduces the ability path by only one-fourth (from the .538 in row three to .424). Finally, as with the younger boys, the path coefficient for school type is significant but still not very large (.257 compared with .174 for the younger boys).

Though there seems little doubt that the English boys obtain a more realistic idea of their probable educational attainments earlier than the American boys do, the findings for the American high school seniors indicate that the American expectations eventually become quite realistic. When the antecedents of the seniors' expectations are compared with the antecedents of educational attainment, the seniors' expectations seem to be more

realistic than even those of the fourth-form English boys.

Of course it can be argued that it is equally unfair to compare fifteen-year-old English boys with seventeen-year-old Americans as it is to compare thirteen-year-olds who are, to different degrees, removed from entry into the adult world. There is no real solution to this problem, since the two educational systems function in such different ways. Whichever comparison is made, though, the English emphasis on the significance of ability stands out. What also stands out is the "free-floating" quality of early American expectations, expectations that evidently become increasingly more firmly linked to social origins and ability as the boys pass through high school.

Conclusion

If we return to the original question concerning how realistic the educational expectations of adolescents are in the two countries, the answer appears to be more complex than anticipated. There is no doubt that the English boys' expectations correspond more fully with the predicted outcomes in early adolescence, and it is clear that both social origins and ability contribute significantly to an explanation of their expectations. In contrast, the young American boys' expectations have little relation to either their social origins or their ability. All of this is consistent with the anticipated greater realism in England and with the English system's emphasis on ability in the process of sponsored mobility.

Yet, the detailed analysis indicates that the English boys' expectations are more strongly influenced by ability than actual educational attainments are. If anything, the English boys are overly impressed with the importance of ability. This overemphasis on ability continues into the fourth form, the point at which most English boys leave school. In contrast, the American boys' expectations become much less free-floating by the time they reach their senior year in high school, and their expectations are related to ability and social origin in a manner that is very similar to the relationship between these

antecedents and actual educational attainments. By that definition, the American seniors are the most realistic of all the groups of boys studied.

INTELLIGENCE AND DELINQUENCY: A REVISIONIST REVIEW

TRAVIS HIRSCHI AND MICHAEL J. HINDELANG

State University of New York, Albany

American Sociological Review 1977, Vol. 42 (August):571-587

Recent research on intelligence and delinquency suggests that (1) the relation is at least as strong as the relation of either class or race to official delinquency; (2) the relation is stronger than the relation of either class or race to self-reported delinquency. In an analysis of the history of the research on the IQ-delinquency relation, we trace the developments leading to the current textbook position that IQ is not an important factor in delinquency. This position, which came into vogue about forty years ago and is still held by many sociologists, has its roots in: (1) a medical to sociological paradigm shift in this century; (2) the failure of subsequent research to substantiate the early exorbitant claims that low IQ was a necessary and sufficient condition for illegal behavior; (3) early negative reviews of research on this question by Sutherland and others; (4) reservations about the validity of the measurement of both IQ and delinquency; (5) erroneous interpretation of research findings; (6) speculation regarding factors which might account for the relation. It is noted that many currently prominent sociological theories of delinquency implicitly or explicitly use IQ as a crucial theoretical element. We show that IQ has an effect on delinquency independent of class and race, and we argue that this effect is mediated through a host of school variables.

Few groups in American society have been defended more diligently by sociologists against allegations of difference than ordinary delinquents. From the beginning, the thrust of sociological theory has been to deny the relevance of individual differences to an explanation of

delinquency, and the thrust of sociological criticism has been to discount research findings apparently to the contrary. "Devastating" reviews of the research literature typically meet with uncritical acceptance or even applause, and new theories and "new criminologies" are con-

structed in a research vacuum, a vacuum that may itself claim research support.

A major source of this stance toward individual differences is the notion widely held in the field of deviance that "kinds of people" theories are non- or even anti-sociological. Most of the major theorists in the area (Sutherland, Merton, Cohen, Becker) have more or less explicitly argued this point, and efforts to bring criminology "up-to-date" with the rest of sociology frequently imply that interest in individual differences is an outmoded relic of the field's positivistic past (e.g., Matza, 1964; Taylor et al, 1973). Another source of this stance toward difference is frankly moral. According to Liazos (1972), who provides extensive documentation, sociologists repeatedly assert that deviants are "at least as good as anyone else." If Liazos' analysis is any guide, we may assume it is easy to, confuse the moral-evaluative "as good as" with the empirical "the same as." For example, Liazos goes on to argue that the repeated assertion that "'deviants' are *not different*" may raise the very doubts we want to dispel." Sociologists have observed for some time that, "always and everywhere, *difference* is the occasion and excuse for ignoring the equal claims of others" (Ross, 1901:25). They therefore feel duty-bound, it seems, to protect delinquents from those who would justify abusing them on these grounds.

Among the many possible individual differences between delinquents and non-delinquents, none is apparently more threatening to the integrity of the field and to its moral commitments than IQ. To the standard list of scientific and moral arguments against IQ, the sociological student of crime and delinquency can add the weight of a half-century struggle against biological theories and the predatory social ethic they are alleged to foster. In fact, the single argument against IQ developed within criminology is sufficiently simple and persuasive that the standard list need not be invoked. At the time criminology became a subfield of sociology, marked differences in IQ between delinquents and nondelinquents were pretty much taken for granted, and a major task confronting those wishing to

claim the field for the sociological perspective was to call these alleged differences into question. This task was successfully accomplished. IQ, it was confidently suggested, doesn't matter (see Sutherland, 1924:108). Today, textbooks in crime and delinquency ignore IQ or impatiently explain to the reader that IQ is no longer taken seriously by knowledgeable students simply because no differences worth considering have been revealed by research.

As we shall show, the textbooks are wrong.¹ IQ is an important correlate of delinquency. It is at least as important as social class or race. This fact has straightforward implications for sociological theorizing and research, most of which has taken place within the context of official denial of IQ differences. Its implications for social policy are variably straightforward and are, in any event, strictly irrelevant to questions of the current impact of IQ on delinquency: the actual relation between IQ and delinquency must be the standard against which all arguments, including our own, are judged.

The Current Textbook View

Many textbooks do not even mention IQ (e.g., Gibbons, 1970; Bloch and Geis, 1962). Most, however, introduce the subject and then argue against its significance. The basic position is that there are no differences in IQ between delinquents and nondelinquents. The research and reviews most frequently cited in support of this conclusion are now over forty years old (e.g., Murchison, 1926; Sutherland, 1931; Zeleny, 1933). The tendency to rely on summaries provided by other textbooks, especially, in this case, those written by psychologists, is much in evidence.

Despite the selectivity of textbook summaries of the evidence, most of them leave the reader with the distinct impression that IQ may be a very important

¹ In a more general treatment of the measurement and correlates of delinquency, Gordon (1976) independently reaches conclusions about the importance of IQ that are very close to those reported here.

cause of delinquency after all. Few textbook writers seem able to resist additional arguments that have the effect of undercutting their basic position:

It is now generally recognized that so-called intelligence tests tend to measure the degree to which the individual has assimilated and internalized middle-class values rather than intelligence.

We could anticipate that a feeble-minded individual would be more readily incarcerated than other individuals. (Haskell and Yablonsky, 1974:216)

It is not mental deficiency per se which results in crime; rather the inability of a mentally deficient person to make adequate social adjustments. . . . (Johnson, 1968:173)

Although a higher percentage of delinquent children come from the ranks of the mental defective, particularly from those of borderline intelligence, it is not the mental deficiency per se but the inability of the child to make adequate school or social adjustments that usually results in delinquency. (Sutherland and Cressey, 1974:174, quoting Coleman, 1950)

The great proportion of persons with low intelligence scores undoubtedly are non-deviants, whereas there are large numbers of persons with above normal intelligence who are. (Clinard, 1968:170)

All of these arguments take for granted a negative correlation between IQ and delinquency. The "middle-class values" interpretation of IQ tests suggests that scores on these tests may well be the strongest predictor of delinquency available. The "not per se" argument asserts that the relation is, in fact, causal in the usual meaning of the term—i.e., non-spurious. The "more readily incarcerated" view contradicts the "not per se" argument by suggesting a direct link between IQ and, at least, official delinquency. And the "great proportion" argument asserts only that the relation is not perfect. Still, the current view, simply stated, is that IQ makes no difference. This view is not supported by the results of research.

Recent Research on Official Delinquency

At least half a dozen recent studies permit examination of the effects of IQ on

official delinquency. These studies have been conducted in diverse settings, they rely on a variety of measures of IQ and of delinquency, and they all employ some measure of control for the effects of such variables as social class and race. All of them show IQ to be an important predictor of official delinquency.²

How strong is this effect? Since social class and race are considered important correlates of official delinquency by almost everyone, they should provide a sufficiently stringent criterion and be available for comparison. Further, since both class and race are frequently used to discount the effects of IQ, this comparison will provide evidence relative to the common argument that IQ effects are merely a by-product of race and class effects.

IQ, Social Class and Official Delinquency

Reiss and Rhodes (1961) examined the juvenile court records of more than 9,200 in-school white boys in Davidson County, Tennessee. Using three-category divisions on occupational status of the head of household and on IQ, they found that the rate (per 100) of court adjudication ranged from 5.7 in the high to 9.6 in the low status groups, and from 4.8 in the high to 10.3 in the low IQ groups. In other words, the rate of adjudication in the lowest occupational group was 1.7 times that of the highest occupational group, while the rate of the adjudication in the lowest IQ group was 2.1 times that of the highest IQ group.³ Since the distributions of occupational status and IQ were roughly comparable, in the Davidson County data IQ is more important than social class as a predictor of official delinquency among white boys.

Hirschi (1969) examined the police rec-

² Unless otherwise noted, all references to "the relation between IQ and delinquency" assume an inverse correlation.

³ When father's occupational status was dichotomized and IQ trichotomized, the two variables were shown to have independent effects, with some tendency toward interaction: the effects of occupational status were more marked as IQ decreased, which also says that the effects of IQ were more marked for blue-collar than for white-collar boys.

ords of over 3,600 boys in Contra Costa County, California. Since previously published analyses do not directly compare the effects of social class and IQ, we have reanalyzed these data, with the results shown in Tables 1 and 2 (for details of data collection, see Hirschi, 1969:35-46).

In these data, the effect of IQ on official delinquency is stronger than that of father's education. Among whites, the gamma for the relationship between IQ and delinquency is $-.31$, while the comparable gamma for father's education is $-.20$; among blacks, the gammas are $-.16$ and $-.05$, respectively. Although the data are not shown, a composite measure of family status which includes employment and welfare status, presence of the father, and education and occupation of the parents shows results comparable to those for father's education in both racial categories. For whites, the gamma is $-.18$; for blacks, it is $-.09$. When the effects of this measure of family status and IQ are examined *simultaneously* within racial groups, the results are consistent with the zero-order relations. Both family status and IQ are independently related to official delinquency; the superiority of IQ in comparison with family status, however measured, is especially noticeable among blacks.

Wolfgang et al. (1972) obtained IQ scores on 8,700 of the 10,000 boys in their Philadelphia cohort. They do not present measures of association for these IQ scores and delinquency, nor do they show tabular material in which IQ is treated as an independent variable. They do, however, present average IQ scores by

number of contacts with the groups homogeneous on class. The differences in average scores for chronic offenders and non-offenders range from nine IQ points among low socioeconomic status nonwhites to thirteen IQ points among low socioeconomic status whites (Wolfgang et al. 1972:93). Again, although no direct comparison with social class is possible, the Philadelphia data reveal a strong relationship between IQ and delinquency independent of social class.

West (1973:84) followed 4,000 boys over a ten-year period and compared the delinquent and non-delinquent groups on the prevalence of low IQ. In the same way [he] compares other factors such as poverty, family status, or criminal parents.' The relationship between IQ and delinquency in West's data is substantial. One-quarter of those with IQ scores below 90 more had a police record, than one-half of those with IQ scores of 90 or less. Even more impressively, only one in fifty boys with an IQ of 90 or less was a recidivist, one in fifty with an IQ of 90 or less fell in the recidivist category. West (1973:84-5) concludes from his thorough analysis that 'low IQ is a significant precursor of delinquency to much the same extent as other factors.' Although he reports a strong relationship between family income and delinquency, in American studies, IQ was able to explain delinquency on equal terms and to supplant family income and several other factors of family culture were controlled in the matching procedure.

It should be noted that the differences in delinquency produced by IQ in West's data reflect a difference of about 12 points between non-offenders and recidivists—a difference within the range of the race-specific differences calculated from Wolfgang et al. data. West's results, with those of Wolfgang et al., suggest that the effect is largely attributable to chronic offenders (recidivists), which may

Table 1. Percent Committing Two or More Official Delinquent Acts by IQ (Stanford Binet) and Race^a

	IQ				
	0-19	20-39	40-59	60-79	80-99
White males	22.6 (204)	25.6 (282)	14.6 (309)	8.4 (341)	6.2 (403)
Black males	38.2 (429)	36.2 (273)	26.2 (153)	19.7 (71)	19.0 (42)

^a IQ scores are shown as percentiles. Gammas, calculated on the entire range of delinquency scores (0-4), are $-.31$ for whites and $-.16$ for blacks.

⁴ Wolfgang et al. used the Philadelphia Ability Test. The typical IQ test has a standard deviation of 15.

Table 2. Percent Committing Two or More Official Delinquent Acts by Father's Education and Race^a

Race	Father's Education				
	Less than High School Grad.	High School Graduate	Trade or Business	Some College	College Graduate
White Males	17.7 (356)	14.3 (485)	13.4 (82)	8.0 (201)	7.8 (306)
Black Males	33.8 (343)	34.4 (209)	42.1 (57)	30.8 (123)	19.1 (84)

^a Gammas, calculated on the entire range of delinquency scores (0-4), are -.20 for whites and -.05 for blacks.

the relatively weak performance of IQ in studies of self-reported delinquency.

IQ, Race and Official Delinquency

Comparison of the effects of race and IQ is more difficult than the class-IQ comparison because of a greater paucity of data or, at least, of appropriately analyzed data. There can be no doubt that IQ is related to delinquency within race categories. All of the studies mentioned are consistent on this point. The relative strength of the two variables is, however, open to question.

The multiple regression analysis using number of offenses as the dependent variable presented by Wolfgang et al. (1972:275-9) includes both race and IQ. Unfortunately for present purposes, it also includes highest grade completed and number of school moves, variables which account for the bulk of the explained variance in this measure of delinquency. Thus, the fact that race places third behind these school variables and IQ accounts for virtually nothing cannot be taken as direct evidence of their relative importance. We know that IQ is strongly related to delinquency in the Wolfgang

data independent of race. We know, too, that IQ is strongly related to the school variables ($r=.468$ for highest grade completed) that, in variance terms, do most of the work. Therefore, we know that if these intervening variables were excluded from the analysis, the proportion of variance accounted for by IQ would increase substantially.

In the Contra Costa data, IQ and race have virtually identical effects on official delinquency. For illustration, we compare a dichotomous measure of IQ with the two categories of race in Table 3.

Measures of association between IQ and delinquency and between race and delinquency reflect the percentage differences in Table 3: race and IQ are virtually identical in their ability to predict delinquency. For race, $r=.26$; for IQ, $r=.27$.

The findings of McCord and McCord (1959:66, 203) from the Cambridge-Sommerville Youth Study are sometimes cited (e.g., West, 1973:91) as showing "no connection between low IQ and delinquency." Although in the McCords' data those in the lowest IQ group (80 or below) did have an intermediate rate of conviction during the follow-up period,⁵ within the normal range of IQ scores (above 80) there was a monotonic decrease in rates of conviction from almost one-half in the 81-90 IQ group to one-quarter in the 110 or more IQ group. Because those in the lowest IQ group are only ten percent of

Table 3. Percent Committing Two or More Official Delinquent Acts by IQ and Race^a

Race	IQ	
	Low	High
White males	24.3 (486)	9.4 (1053)
Black males	37.6 (702)	23.3 (266)

^a IQ scores dichotomized at the 40th percentile.

⁵ Our figures are for the experimental and control groups combined (McCord and McCord, 1959:66, 203). Strictly speaking, the McCord data apply to adult criminality as well as juvenile delinquency, since the average age of their subjects was 27 at the time data on convictions were obtained.

the sample, the McCords' data, too, show an inverse relation between IQ and official misconduct.

Such problems of interpretation do not arise in Short and Strodtbeck's (1965) study of gang delinquency in Chicago. They report that gang boys scored lower on "all six intelligence measures" than non-gang boys in the same (lower) class; this difference held for white and black respondents alike.

Toby and Toby (1961) found "intellectual status" to be a significant forerunner of delinquency independent of socioeconomic status. And Reckless and Dinitz (1972) found that their teacher-nominated "good" boys had IQs from 8 to 12 points higher than their teacher-nominated "bad" boys in a class-homogeneous area.⁶

All in all, it seems reasonable to conclude on the basis of currently available data that IQ is related to official delinquency and that, in fact, it is as important in predicting official delinquency as social class or race. We know of no current research findings contrary to this conclusion.

Self-Reported Delinquency

A significant consequence of the no-IQ-difference position was that it helped set the stage for extensive use of self-report methods of measuring delinquent behavior. This position explicitly asserts that delinquents are as likely as others to possess the various skills reflected by IQ tests. If, however, the assumption of equal ability is unfounded, the measurement of delinquent behavior by the self-report method may be confounded with IQ, i.e., those most likely to commit delinquent acts may be least able to report adequately on their behavior. The self-report method, especially questionnaires,⁷

therefore does not provide an unambiguous test of the hypothesis that IQ is related to delinquent behavior.

In any event, most studies do find a relation between IQ and self-reported delinquency, but this relation is less robust than that found in official data. At one extreme, West (1973:158) found that 28.4 percent of the worst quarter of his sample on self-reported delinquency had low IQs, as compared to 16.6 percent in the remaining three-quarters—a difference only slightly smaller than his finding for official delinquency.

Weis (1973), too, found differences as strong as those typically reported when delinquency is measured by official data. In his study in a white upper-middle-class community near San Francisco, Weis collected Wechsler-Bellevue IQ scores and self-reports of delinquency for 255 male and female eleventh-grade students. One of the clusters emerging from his analysis was a property deviance scale that included items on theft, burglary, shoplifting and vandalism. When these scores were trichotomized, Weis found that 27 percent of those with IQ scores of less than 110, and 49 percent of those with IQ scores of 110 or more, had low scores on the property deviance scale. He found a similar difference (23% versus 41%) on a social deviance scale that included items on marijuana, alcohol and gambling.⁸

More typical of self-report studies, however, are the relations from the Contra Costa data shown in Table 4. Among white males, twice the proportion in the lowest as in the highest IQ group report involvement in two or more of a possible six delinquent acts; among black males the comparable ratio is 3:2.

Whatever the strength of the relations in Table 4, we believe they should be evaluated by comparison with social class and race. As Table 4 shows, race has no impact on self-reported delinquency—a finding consistent with much of the self-report literature (e.g., Williams and Gold, 1972). The same literature has consistently re-

⁶ The Toby-Toby and Reckless-Dinitz studies may be marginal to the question of IQ effects. However, this concern would carry greater weight if their results were contrary to research focusing directly on the IQ question.

⁷ Early warnings that the questionnaire method is especially limited by the high rates of illiteracy among delinquents (Erickson and Empey, 1963) have gone essentially unheeded.

⁸ For details of data collection, see Weis (1973). The data reported in the text cannot be found in Weis' dissertation. We are grateful to him for making them available to us.

Table 4. Percent Committing Two or More Self-Reported Delinquent Acts by IQ and Race ^a

Race	Low IQ				High IQ
White males	24 (196)	26 (270)	20 (302)	19 (336)	12 (396)
Black males	27 (393)	26 (257)	19 (149)	19 (68)	18 (39)

^a IQ scores are grouped in percentiles as in Table 1. Gammas, calculated on the entire range of delinquency scores (0-6), are -.15 for whites and -.07 for blacks.

vealed a weaker relation of social class (e.g., Nye et al., 1958; Akers, 1964) to self-reported delinquency than that found in Table 4. The weight of the evidence is that IQ is more important than race and social class. The voluminous criticisms advanced against self-report delinquency research—with an eye to rescuing social class—presumably would have the same or even greater consequences for IQ. For example, the heavy reliance on in-school populations, the overabundance of minor offenders, and the dependence on subject cooperation may work to attenuate the relationship between social class and delinquency. If so, there is reason to believe that these factors would also depress the relation between self-reported delinquency and IQ. In fact, Hirschi (1969:46) reports that among those with the highest grades in English who had no police records, 79 percent cooperated with the self-report survey, while among those with the lowest grades in English who had police records, only 38 percent cooperated. More importantly, not only did grades in English and official delinquency substantially affect cooperation with the self-report survey, the two factors were found to interact: low ability boys with police records were disproportionately unlikely to appear in the self-report sample. Since official delinquents are likely to be "self-report" delinquents (if sampled), the number of self-reported delinquents in the sample is considerably depressed, especially at the low end of the ability scale.

In short, however delinquency is measured, IQ is able to compete on at least equal terms with class and race, the major

bases of most sociological theories of delinquency. At the same time, a relation between IQ and delinquency is routinely denied in sociological textbooks.

Implications for Theory

Our original purpose in introducing theory was frankly argumentative: we expected to find theorists struggling with a conflict between their own logic and the erroneous "results of research" on IQ. In short, we expected to find that they had often been led astray by the anti-IQ climate of criminology.

Actual examination of currently influential theories required revision of our plans. In most cases, theorists were not paying all that much attention to the "results of research." We had been led astray by the naive textbook assumption that theory organizes research and research tests and modifies theory. In the case of IQ, however, it would be more accurate to say that theory opposes research and research ignores theory.

Theories from the period (Merton, 1938; Sutherland and Cressey, 1974) when most researchers considered low IQ a strong correlate of delinquency ignore this variable,⁹ while theories from the period when IQ was almost universally considered irrelevant predict either very strong negative (Cohen, 1955) or weak but important positive relations (Cloward and Ohlin, 1960) with delinquency. And a theoretical tradition (labeling) spanning both periods has managed to take a position opposite to research in both of them. Although all of these theories have been heavily researched, investigators have paid little or no attention to their views regarding IQ.

Since it is difficult to argue with those who agree, we will briefly show that resistance to consideration or inclusion of IQ does not characterize any current theory; that, on the contrary, several important theories require a relation between IQ and delinquency. Explicit recognition of this

⁹ The Gluecks reported periodically throughout the thirties that their delinquents were "burdened with feeble-mindedness" (e.g., Glueck and Glueck, 1934).

fact would only increase their scope, the plausibility of their claims, and their consistency with research findings.

The best example is Cohen's (1955) effort to relate social class to delinquency by way of differential experience in the educational system. In Cohen's theory, children differentially prepared or qualified encounter a school system that treats all comers alike. Children inadequately "prepared" for success in school find the experience painful and are likely, as a consequence, to turn to delinquency. The place of IQ in this process would seem obvious and, in fact, Cohen (1955:102-3) could not be more explicit on this question:

It may be taken as established that ability, as measured by performance in conventional tests of intelligence, varies directly with social class. . . . The conventional tests do test for abilities that are highly prized by middle-class people, that are fostered by middle-class socialization, and that are especially important for further achievement in the academic world and in middle-class society. In short, *the results of these tests are one important index of the ability of the child to meet middle-class expectations, to do the kinds of things that bring rewards in the middle-class world.* (emphasis added)

In Cohen's theory, intelligence intervenes between social class and delinquency or it is at least an important indicator of the social class of the *child*. In either case, IQ should be more strongly related to delinquency than such indirect measures of the ability of the child to meet middle-class expectations as "*father's* occupation."

Cohen's views on the interchangeability of IQ and class illustrate how the former could have been used to extend the scope of his theory beyond the confines of "lower-class delinquency." The situation facing the middle-class child with low IQ may not be all that different from the situation facing the lower-class child and, if such a situation explains the delinquency of one of them, it may explain the delinquency of the other as well. If both lower- and middle-class delinquency can be explained by the same mechanism, Cohen's reliance on a separate mechanism for middle-class boys (Cohen, 1955:162-9) is

inexplicable or is, at the very least, theoretically and empirically inelegant.

If a zero relation between IQ and delinquency would falsify Cohen's theory, it would virtually falsify the theory of Cloward and Ohlin (1960) as well, but for quite different reasons. Cloward and Ohlin (1960:111) suggest a positive relation between intelligence and delinquency:

Some persons who have experienced a marked discrepancy between aspirations and achievements may look outward, attributing their failure to the existence of unjust or arbitrary institutional arrangements which keep men of ability and ambition from rising in the social structure. Such persons do not view their failure as a reflection of personal inadequacy but instead blame a cultural and social system that encourages everyone to reach for success while differentially restricting access to the success-goals. In contrast to this group there are individuals who attribute failure to their own inadequacies—to a lack of discipline, zeal, intelligence, persistence, or other personal quality.

In other words, the lower-class boy with a high IQ whose talents go unrecognized and unrewarded is a prime candidate for delinquency.

On the basis of available evidence, Cloward and Ohlin are wrong. For present purposes, however, the point is that their theory requires research on the IQ of juvenile offenders and is enduring testimony to the dangers in the view that IQ need be "no longer seriously considered" by criminologists.¹⁰

At first glance, labeling theory would seem to be an exception to our argument that IQ is important, since this theory puts no stock in the notion that individual differences may act as causes of delinquent behavior. In one of the first efforts by a labeling theorist to neutralize individual-difference research, Tannenbaum (1938:6) focused special attention on IQ, arguing that "whatever 'intelligence' is, it has no demonstrated relationship to crime." As labeling theory has "progressed," how-

¹⁰ Although Merton (1938) ignores IQ and its "success" implications, IQ is obviously relevant to any opportunity theory.

ever, as it has become more closely associated with the conflict perspective according to which "society organizes itself for the protection of the ruling classes against the socially inferior" (Doleschal and Klapmuts, 1973:622), it has tended more and more to recognize that it too is dependent on individual differences. The generally low IQ of official delinquents is now accepted by labeling theorists and is used as evidence for their view that the system discriminates against or creates the disadvantaged (Doleschal and Klapmuts, 1973:612, 616; Polk and Schafer, 1972:34-54).

If labeling theorists argue that discrimination produces the relation between IQ and delinquency, then the mechanism that connects IQ to delinquency is the bone of contention between labeling and conventional theories—not the fact of a relation itself. We will return to the mechanism question.

Perhaps the only major theory strictly silent on the question of IQ is Sutherland's "differential association" (Sutherland and Cressey, 1974:75-7). Sutherland (1931) played a major role in constructing the current position of criminology on IQ. He rejoiced in its alleged failure to discriminate between delinquents and nondelinquents, and his influential text continues to belittle "mental testers" to the present day. Even so, differential association has nothing to fear from intelligence. This theory faintly suggests a positive association among those exposed to the delinquent culture (as does any theory that emphasizes the need to learn crime), but it really cannot be used to predict even the sign of the relation in the general population. If the theory cannot predict the sign of this relation, it is, nonetheless, capable of accounting for any relation between IQ and delinquency that might be revealed by research.

A final set of theories might be grouped under the heading of "social control" (for a convenient summary, see Nettler, 1974). These theories focus on a broad range of causal variables, and they are relatively open to individual differences, to the idea that "in learning to conduct ourselves, some of us need more lessons than

others" (Nettler, 1974:232). Although none of them may now consider IQ of central importance, most suggest a negative association, and none would have difficulty absorbing this variable. In fact, for those sociologically-oriented control theories that emphasize "stakes in conformity" (e.g., Toby, 1957), IQ is of obvious importance.

Most sociological theories, then, have been saying for some time that IQ should be related to delinquency for the same reason that social class is, or should be related to it. Given the theoretical overlap of IQ and social class, the contrast in how the research community has reacted to their varying fates would be hard for an outsider to understand.

The finding that social class was unrelated to self-reported delinquency produced a large volume of follow-up research. The "finding" that IQ was unrelated to any measure of delinquency was, in contrast, accepted without so much as a murmur of protest. The literature on IQ contains none of the "what may have gone wrong" kinds of methodological critiques so often encountered in efforts to save social class. Instead, it is marked by considerable speculative ingenuity directed against an established relation. The extent to which this relation has been established may be revealed by a review of the history of IQ testing as it applies to delinquency and crime.

History

As a cause of delinquency, IQ got off to a very strong start in the first years of this century. The notion that "imbeciles" and "idiots" would be unable to resist criminal impulses or, for that matter, even to distinguish right from wrong, was a straightforward extension of Lombroso's then prestigious theory of the born or biologically defective criminal. Initial research did nothing to dampen enthusiasm for this idea. Goring (1972:255) in Great Britain reported that criminals "as a class, are highly differentiated mentally from the law abiding classes," and Goddard (1914:7) in the United States concluded that "probably from 25% to 50% of the

people in our prisons are mentally defective and incapable of managing their affairs with ordinary prudence." In the period 1910–1914, the "percentage feeble-minded" in fifty studies of institutionalized delinquents had a median value of 51 (Sutherland, 1931:358). Since it was then assumed that the proportion feeble-minded in the general population was less than one percent (Goring used an estimate of .46 percent), the conclusion that faulty intelligence was the "single most important cause of crime" followed, or at least seemed to follow directly from the evidence.

If we follow the fate of IQ through mainstream criminology, we discover that its day was very brief. Less than two decades after Goring estimated .6553 as a "minimum value" for the correlation between mental defectiveness and crime, Sutherland (1931) was poking fun at the absurdities of the "mental testers."¹¹ His negative review of their research was so influential that the "modern" or "recent" position on IQ described by today's textbooks appears to have been firmly established at that time, i.e., forty-five years ago.

Sutherland's stance is not difficult to understand. As Savitz (1972:xviii) has reminded us, the medical profession seized power in criminology before the end of the nineteenth century and still maintained a preeminent position in the early days of intelligence testing—both Goring and Goddard were physicians. A short time later, however, criminology had become a subfield of sociology. Given this shift in disciplinary dominance, an equivalent

paradigm shift is now pretty much accepted as a logical necessity. "Intelligence" was a central element of the "old" paradigm. It just had to go. And go it did.

The history of IQ in research findings is not so quickly or easily told. The initial claims about the proportion of feeble-minded delinquents were excessively high because—as Merrill (1947:159) has pointed out—researchers were basing their cutting point on children in institutions for the mentally deficient. The logic of this procedure went something like this: if no child in an institution for the feeble-minded has a mental age in excess of twelve, then a mental age of twelve or less is sufficient to classify a person feeble-minded. There was nothing especially silly about this procedure, it merely made the mistake of assuming that the same procedure would not also classify a large portion of the general population feeble-minded. As it became apparent that a too-large portion of the general population would be classified feeble-minded, the mental age requirement was first abruptly and then gradually lowered, with the result that the proportion feeble-minded among delinquents also first abruptly and then gradually declined. Sutherland (1931) called attention to this twenty-year trend—which, in fact, continued for another 30 years (Woodward, 1955; Caplan, 1965)—and allowed his readers to conclude that it would continue until the initial claims of difference between delinquents and nondelinquents had no foundation in fact.

The most direct evidence against an IQ difference resulted from the extensive testing of the draft army in World War I. Murchison (1926) and Tulchin (1939) reported that the distribution of intelligence in the draft army was virtually identical to the distribution among adult prisoners. Without including details of the investigation, Murchison also reported that the prisoners in a certain midwestern institution were more intelligent than the guards, an anecdotal fact even now more widely quoted than the results of many carefully conducted studies showing important differences in favor of the intelligence hypothesis. Although Sutherland (1931:364) acknowledged that "serious questions

¹¹ Sutherland summarized about 350 studies conducted between 1910 and 1928 noting downward trends in the proportion feeble-minded in delinquent and criminal groups, as well as inconsistencies in the results. "In those early days of mental testing the influence of Goddard was very great; he had asserted that the more expert the mental tester the larger the proportion of delinquents he would find to be feeble-minded. Many of the testers attempted to demonstrate their superiority in that manner." "Consequently a report regarding the proportion of a delinquent group feeble-minded is of primary significance in locating the mental tester upon a scale of mental testing methods. In this sense the psychometric tests of delinquents throw more light upon the intelligence of the mental testers than upon the intelligence of delinquents." (Sutherland, 1931:358–62).

have been raised regarding the validity of these tests and the validity of using the draft army as a sample of the general population," he carefully noted that "the consistency in results is a fact that cannot be overlooked."

By the late 1920s and early 1930s, the evidence was sufficiently mixed that summaries of the research literature were arriving at variant conclusions. Thomas and Thomas (1928:365) concluded from their review of the same literature examined by Sutherland that important differences between delinquents and non-delinquents on IQ were "beyond question." They reached this conclusion by focusing on the many studies reporting such differences and by discounting the draft-army research as being so clearly out of line as to be suspect. In 1935, Chassell published an extensive review of research on this question. Her general conclusion, based on nearly 300 studies:

Undoubtedly the relation between morality and intellect in the general population is considerably higher than usually found in restricted groups. Nevertheless, it is hardly probable that this relation is high. Expressed in correlational terms, the relation in the general population may therefore be expected to fall below .70. (Chassell, 1935:470)¹²

As IQ tests improved, the average score of samples of delinquents also improved until, with the advent of the Revised Stanford Binet and the Wechsler-Bellevue scales in the late 1930s, they were obtaining an average IQ of about 92 (Merrill, 1947; Woodward, 1955; Caplan, 1965). With the advent of these improved tests about 35 years ago, the marked trends and occasional fluctuations of earlier research apparently came to an end. Since that time, it has been reasonable to expect that samples of delinquents would differ from the general population by about eight IQ points. This conclusion has been accepted by Woodward (1955) and Caplan (1965) in

major reviews of the literature and is generally consistent with the more recent research reviewed in this paper.

The question, then, is how a reliable eight IQ point difference was converted to the no-difference conclusion of the textbooks. One possibility is that an eight IQ point difference was not seen as theoretically or practically important. This possibility is easily disputed: no modern reviewer has questioned the importance of a difference of this magnitude.¹³ Assuming that ten percent of the population is delinquent, this difference would produce a correlation (Yule's Q) between IQ and delinquency of about -.4.

The neglect of IQ after a reliable and important difference had been established may be traced to the initial plausibility of an unusual number of counter-arguments. These arguments are so numerous and diverse that we can hope to deal with them only generally and briefly.

The Spuriousness Argument

Scholarly reviews of the literature have made much of the hypothesis that the low IQs of delinquents are a spurious consequence of differences in class or culture. Against the estimated eight IQ point difference between delinquents and non-delinquents, Woodward (1955) assembles a good deal of material suggesting the possibility that cultural factors are at work: the children of professionals differ from those of unskilled manual workers by about 20 IQ points; average IQ scores are low in *areas* with high delinquency rates;¹⁴ children in large families have low IQ scores and are more likely to be delinquent; overcrowding is related both to low IQ and to delinquency; finally, studies based on sib-sib comparisons (such as Healy and Bronner, 1936) and on other methods of control for cultural factors

¹² Present-day researchers would not be so modest about a correlation of .70! Chassell's caution may be indicative of the standards against which empirical relations were judged in the early days of quantitative research. These standards may account for the ease with which reviewers were able to reject IQ as a "significant" causal variable (see also footnote 1).

¹³ Caplan (1965:104) refers to this eight-point difference as a "first class" relationship. As noted below, however, he cautions the reader that cultural factors be taken into account before it is accepted as genuine.

¹⁴ This is an example of what might be called the reverse ecological fallacy: because IQ and delinquency are related at the ecological level, it is *unlikely* that they are related at the individual level.

"tend to support the contention that complete control *would* eliminate the difference between delinquents and non-delinquents" (Woodward, 1955:289; emphasis added).¹⁵ As we have seen, the evidence says otherwise. Differences by class and race do not account for IQ differences between delinquents and non-delinquents. These differences remain pronounced within groups homogeneous on these variables. If there exists a cultural correlate of both IQ and delinquency strong enough to account for the relation between them, it has not yet been identified.

Ten years after Woodward's influential review (see Wootton, 1959:302), Caplan (1965) was unable to find additional research material bearing directly on her cultural hypothesis. His conclusions about the effects of IQ are, however, if anything, more skeptical than Woodward's, because he is able to cite an additional source of concern.

Arguments Focusing on the Measurement of Delinquency

The advent of the self-report method helped Caplan (1965:120-1) call into question the measures of delinquency upon

which the original findings of IQ differences were based. Once again, the evidence against IQ was inferential rather than direct: if official data measure delinquency imperfectly, then imperfections in measurement rather than the phenomenon itself may account for the observed relation. And, indeed, few have been able to resist ascribing IQ differences between officially identified delinquents and non-delinquents to the ability of the bright delinquent to avoid detection or to differential response of officials to high and low IQ adolescents (e.g., Sutherland, 1931; Doleschal and Klapmuts, 1973; Stark, 1975).

Both the differential detection and differential reaction hypotheses require that IQ have a direct or independent effect on official delinquency.¹⁶ Such direct effect hypotheses compete with intervening variable hypotheses and may be directly tested when the latter are available. A competing hypothesis widely mentioned in the literature (e.g., Short and Strodtbeck, 1965:238; West, 1973:44) is that IQ affects delinquency through school performance. If IQ has the direct effect suggested by the differential detection and reaction hypotheses, nothing consequent to IQ can explain the zero-order relation. Two studies bear on this question. When Wolfgang et al. removed by statistical adjustment the effects of such intervening variables as highest grade completed, the relation between IQ and such "detection" measures as number of offenses virtually vanished (Wolfgang et al., 1972:275-9). (We have replicated this finding with the Contra Costa County data.) Taking a somewhat different approach, West (1973:217) also was able to reduce the relation between IQ and official delinquency below the significant level by matching on peer and teacher ratings on "troublesomeness." These ratings were made at ages eight and ten, well before the delinquent acts recorded by officials. Once again, then, *the*

¹⁵ Healy and Bronner (1936) controlled cultural factors by matching 105 delinquents with their same sex, nondelinquent sib nearest in age and then comparing IQ test scores. Although they found an IQ difference in favor of the nondelinquents, this difference was not statistically significant and was not interpreted as practically or theoretically significant by them. (Thirty-four percent of the delinquents and 26 percent of the nondelinquents had IQs under 90.)

The difficulty with this widely cited study (e.g., Wootton, 1959) is that its design makes the outcome a statistical necessity. Pushing the logic of Healy and Bronner's matching procedure one step further, we would compare identical twins raised together, only one of whom was delinquent. Since the correlation between the IQs of identical twins raised together is about .87, a figure "nearly as high . . . the correlation between two parallel tests for the same individual" (Eckland, 1967:177), we would be asking whether errors in IQ measurement are related to delinquency. By the same token, knowing that the "control" is a brother or sister reared in the same household tells us a good deal about what to expect in the way of IQ (in most studies the sib-sib correlation is in the neighborhood of .55), and there is little reason to expect the original relation to survive with anything like its "natural" magnitude.

¹⁶ Contrary to the "intelligence per se is not a cause . . ." arguments with which it is often paired, the differential detection argument suggests that, in fact, intelligence per se *is* a cause of delinquency—when delinquency is measured by official records.

differential ability to avoid detection and the differential official reaction on the basis of IQ arguments are not supported by available evidence. (The tests of the official reaction hypothesis are limited by available data to reactions by the police.)

Tests of these and related direct effect hypotheses¹⁷ at the same time identify the mechanism linking IQ to delinquency. This mechanism, the data suggest, is performance in and attitudes toward the school. That school variables are strong enough to account for the impact of IQ should come as no surprise. Their significance for delinquency is nowhere in dispute and is, in fact, one of the oldest and most consistent findings of delinquency research (e.g., Thrasher, 1963; Gold, 1970; Hindelang, 1973; Weis, 1973). What should come as a surprise is the easy acceptance of the no-difference-on-IQ conclusion, since the consequences of IQ differences are generally accepted as major predictors of delinquency. This brings us to the most troublesome of the arguments against IQ effects.

Arguments Focusing on the Measurement or Meaning of IQ

The facts we have presented compete with a wide variety of counter-arguments that focus on the meaning or measurement of IQ: "anybody can learn anything" (Eckland, 1967:174-5, quoting Faris, 1961:838), "it is impossible to make intelligence part of any respectable theory" (ASR referee, 1975), "so-called intelligence tests measure only 'test intelligence' and not innate intelligence" (Clinard, 1968:170), and "mainly they [IQ tests] measure the socioeconomic status of the respondent" (Chambliss and Ryther, 1975:373). Excellent discussions of many of these issues are available in the sociological literature (Eckland, 1967;

Gordon, 1975). We will deal only with those counter-hypotheses that have a direct bearing on the relation between IQ and delinquency and that can be addressed to some extent using data already presented.

The cultural bias of IQ tests. The argument against IQ tests most frequently encountered in the sociological literature is that these tests are biased against low-income and minority group children. Specific test items (e.g., "What color are rubies?") are often presented to show the obviousness of this bias (Chambliss and Ryther, 1975:373). Since the groups said to be discriminated against by IQ tests are the same groups with high rates of delinquency, the cultural bias hypothesis is certainly plausible. In form, it is identical to the traditional cultural hypothesis previously encountered and may be tested using the same data. These data show that the bias hypothesis is inadequate: important differences in IQ between delinquents and nondelinquents *within* race and class categories cannot be explained by argument or evidence that these tests are biased in favor of middle-class whites.

The stability of test scores. To the extent that IQ test scores are unstable and subject to subtle social influence; the meaning of a correlation between IQ and delinquency is open to question. It may be that reaction to the misbehavior of the child influences his IQ, that the low IQ child today may be the high IQ child tomorrow, and so on. These possibilities are summarized in assertions that "the scores are highly unstable through time" (Polk and Schafer, 1972:195). Unfortunately for such assertions, they are not consistent with the evidence: the IQs of children at four or five years of age have a correlation of about .7 with their IQs at age 17 (Bloom, 1964); after age ten, test-retest correlations (regardless of the number of years between the tests) fall between the test's reliability and the square of its reliability (Jensen, 1969:18). For that matter, the ability of IQ tests to predict delinquency at some period far removed from their administration is inconsistent with the gross implications of the instability argument.

A fall-back position for those who

¹⁷ Other very old direct effect hypotheses are that IQ differences stem from (1) the inability of the unintelligent to understand distinctions between right and wrong or (2) their inability to foresee and appreciate the consequences of their acts. These hypotheses assume that low IQ children are more likely to be delinquent, regardless of the social consequences (e.g., school difficulties) of their lack of IQ. Again, current data do not appear to support hypotheses of this form.

would argue instability is that these scores *could be* manipulated by simple and straightforward shifts in the environment of the child:

We may treat people differently out of ignorance or prejudice, but the result is the same as if the supposed differences were real. Studies have shown that school children seen as liable to be educationally backward become educationally backward and that, vice versa, children seen as educationally capable become educationally capable. (Taylor et al., 1973:142; see also Polk and Schafer, 1972:46; Schur, 1973:164)

The study cited in support of such arguments is Rosenthal and Jacobson, *Pygmalion in the Classroom* (1968). In this study, students in grades K through 5 in one elementary school were given group-administered IQ tests at the end of the 1964 academic year. The following fall, a random 20 percent of the students were identified to their teachers as students expected to show unusual intellectual gains during the academic year. In May, 1965, all students were re-tested on the same IQ test. Although both the experimental and the control subjects showed IQ gains, the experimental group showed a 3.8 point greater gain, with the bulk of this gain coming in the first and second grades. On the basis of these results, Rosenthal and Jacobson (1968:98) conclude that favorable expectations of teachers "can be responsible for gains in their pupils' IQ's and, for the lower grades, that these gains can be quite dramatic."

Unfortunately, *Pygmalion* has problems. Snow (1969:197) asserts that the study "stands as a casebook example of many of Darrell Huff's (*How to Lie with Statistics*) admonitions to data analysts" and that it "fails to come close to providing an adequate demonstration of the phenomenon" (the effects of teacher expectations on IQ scores). Thorndike (1968:708) begins his similarly negative review with what has turned out to be a prophetic statement:

In spite of anything I can say, I am sure it (*Pygmalion in the Classroom*) will become a classic—widely referred to and rarely examined critically. Alas, it is so defective technically that one can only regret that it ever

got beyond the eyes of the original investigators!

Thorndike concludes that "the basic data . . . are so untrustworthy that any conclusions based upon them must be suspect." And, indeed, this too was prophetic. Elashoff and Snow (1971) report that *none of nine attempts to replicate the effects of teacher expectations on IQ scores has been successful*. One would think that this would be enough to put an end to the "Rosenthal effect." However, Beeghley and Butler (1974:750) still maintain that the effects of teacher expectations on IQ "have been forcefully demonstrated by Rosenthal and Jacobson," and they muddy the waters by citing two "replications" of *Pygmalion*. In the first, "changes in intellectual functioning were not expected" by the investigators themselves (Meichenbaum et al., 1969:307) and in fact, as far as we can determine, IQ was not even a variable in the study. In the second, the author summarizes a variety of research results and concludes the findings do not "provide any direct proof that teacher expectations can influence pupil performance" (Pidgeon, 1970:126). Ironically—for a study which Beeghley and Butler purport to be a replication of *Pygmalion*—Pidgeon (1970:126) notes that the Rosenthal and Jacobson study "would bear repetition, providing conditions could be found for employing a more satisfactory research design." As of now, it is clear that no labeling or expectation effects of the sort alleged by Rosenthal and Jacobson (and widely cited in the crime and delinquency literature) have been established.

Conclusions

The assertion that IQ affects the likelihood of delinquent behavior through its effect on school performance is consistent with available data. The corollary descriptive assertion that delinquents have lower IQs than nondelinquents is firmly established. Both of these assertions are inconsistent with the "no-IQ-difference" view of the textbooks. They are clearly inconsistent with the image of the delinquent in much sociological writing on the subject, and those planning prevention and treat-

ment programs would do well to take them into account.¹⁸

Interestingly enough, most modern theories of delinquency assume (and some explicitly state) that IQ affects delinquency. That their views have been ignored by researchers testing them speaks to the depth of the concern that individual differences are both non-sociological and positively dangerous. In this sense, IQ is doubly significant in that it represents an entire class of variables traditionally ignored by sociological students of crime and delinquency. Variables in this large residual category (virtually everything beyond class, culture, and official processing) will not lose their status as alternative hypotheses simply by being ignored, and they will continue to restrict and even embarrass sociological theory until some effort is made to incorporate them.

For that matter, IQ is a poor example of a variable that may require modification of sociological perspectives. As of now, there is no evidence that IQ has a direct impact on delinquency. The police bias, differential ability to avoid detection, and inability to appreciate moral distinctions hypotheses are not consistent with current data. If the mechanism linking IQ to delinquency is school performance and adjustment, then IQ does not lead away from the arena in which sociological theories have focused their quest for the antecedents of delinquency; rather, it helps illuminate the social processes occurring there.

REDISCOVERING DELINQUENCY: SOCIAL HISTORY, POLITICAL IDEOLOGY AND THE SOCIOLOGY OF LAW*

JOHN HAGAN

Indiana University and University of Toronto

JEFFREY LEON

University of Toronto

American Sociological Review 1977, Vol. 42 (August):587-598

This paper examines a Marxian social historical approach to the study of legal evolution. The emergence of the Marxian perspective and the logic of its premises are reviewed. Using Canadian delinquency legislation as an historical example, it is found that the Marxian perspective assumes a great deal that is unconfirmed (e.g., that this legislation serves the teleologically inferred "basic interests" of an ambiguously identified "ruling class"), asserts other things that are wrong or misleading (that this legislation increased imprisonment, "invented" new categories of youthful misbehavior, created a "specialized labor market" and increased "industrial discipline"), and ignores much that an organizational analysis helps to reveal (that the emergence of probation work as an organizational concern was the prime factor in the development of Canadian delinquency legislation). Implications of these findings are considered.

It is now common to begin sociological discussions of deviance by reaffirming the shift, in the 1960s, from studying the antecedents of rule-breaking behavior to a concern with the origins of legal norms and the statuses that may or may not follow their violation. Equally noteworthy, however, is an increasingly apparent shift from studying the entrepreneurial and organizational origins of legal norms (e.g., Becker, 1963; Gusfield, 1963; Lemert, 1970; Dickson, 1968) and their enforcement (e.g., Wheeler, 1968; Reiss, 1971; Blumberg, 1967), to a more monotheistic focus in the 1970s on class conflict as the independent variable of concern (Taylor

et al., 1973; Quinney, 1975a; Chambliss, 1973; Platt, 1975).

Several recent papers have questioned the accuracy of class conflict propositions about normative dissensus (Rossi et al., 1974) and the enforcement process (Hagan, 1974; Chiricos and Waldo, 1976). These studies have helped stimulate a clarification and reformulation of propositions (Turk, 1976). At the same time, however, the presumed strength of a Marxian conflict perspective continues to be a class-based, social historical approach to the study of legal evolution (Platt, 1973:30; Chambliss, 1974:8; Taylor et al., 1973:266). This paper reviews recent developments in the sociology of law and critically examines the theoretical and empirical usefulness of the class conflict

* Authorship is alphabetized and does not reflect seniority or priority; the authors share equal responsibility for this paper.

approach, using the origins of juvenile delinquency legislation in Canada as its data.

Conflict, Consensus, and the Sociology of Law

It is still less than a decade since most sociologists adopted a rather agnostic view of the "conflict-consensus debate." (For discussion of this debate see Chambliss and Seidman, 1973; Hills, 1971; Chambliss, 1973; Hagan, 1977.) Chambliss (1969:8) expressed a common view when he reasoned that "a resolution of this debate . . . would be premature"; that "in many cases there is no conflict . . ."; and that "the influence of interest groups . . . is but one aspect of the processes which determine the emergence and focus of the legal norms" (Chambliss, 1969:10). However, two years later, Chambliss (Chambliss and Seidman, 1971:19) finds the literature far more conclusive: "Indeed, the empirical studies . . . make it quite clear that the value-consensus model is . . . incapable of accounting for the shape and character of the legal system. . . ."

Similarly, Quinney's (1969:1970) early work contained pluralistic themes and a restrained optimism about legal change. Perhaps nostalgically, Quinney (1969:5) noted that criminal prosecutions emerged in Athens, in the sixth century B.C., and that "this step protected . . . the lower class of Athens from aggression by the rich and powerful." Furthermore, Quinney (1970:41) conceded that "groups . . . similar in power may well check each others' interests . . ." and that "interest groups receive their individual claims in return for allowing other groups to press for their interests." At this stage, he was a reformed pluralist, denying the assumption that a diversity of interests typically is resolved through compromise, but acknowledging that a plurality of interests operate, and clinging to the Poundian hope that "the public interest may become an ideal fulfilled . . ." (Quinney, 1970:42; cf. Pound, 1943).

The "New Criminologists" (Taylor et al., 1973:265-6) responded by arguing that "the view of law as . . . in the hands of 'powerful interest groups,' does not take

us far enough. . . ." Quinney (1975b:193) soon agreed that "from the evidence of radical scholarship, government and business are inseparable." Thus, "whilst pluralists may suggest that there are diverse and conflicting interests among groups in the upper class, what is ignored is the fact that members of the ruling class work within a common framework . . ." (Quinney, 1975:194). Taylor et al. (1975:3) endorse Quinney's new position as a "move to a Marxist economism."

The key proposition in this new Marxian perspective on law creation is that "The criminal law is . . . first and foremost a reflection of the interests and ideologies of the governing class . . ." (Chambliss, 1974:37; see also Quinney, 1975b:192). Chambliss (1974:37) comes closest to identifying this "ruling class," but is ultimately unable to decide "whether that class is private industry or state bureaucracy." Instead, he offers the contradictory conclusion that "government bureaucracies may, in the last analysis, be controlled by those who influence the society's economic resources . . ., but they also have a life and a force of their own . . ." (1974:27). Assuming these two possibilities were not mutually exclusive, which they are, undermining the notion of a *single* ruling class, some significant questions would remain unanswered. For example, how much of private industry and state bureaucracy is to be included within the "ruling class"? How diverse and extensive can these groupings be and still be considered a single "ruling class"? To what extent is there conflict within and between private industries and state bureaucracies? And, under what conditions do various industrial or bureaucratic groups prevail?

Quinney's response to such questions is to argue that "in contrast to pluralist theory, radical theory notes that the *basic interests*, in spite of *concrete differences*, place the elite into a distinct ruling class" (1975b:194, emphasis added). A difficulty with this argument is that "basic interests" are not identified with sufficient specificity to allow a predictive test of legal control strategies presumed to follow from these interests. Thus, one "Marxist criminologist" includes "direct release"

as evidence of an "integrative control" used to perpetuate "state capitalism" (Spitzer, 1975:647-9). Unfortunately, this type of conceptualization encourages tautologous theorizing and, in a manner similar to functionalist formulations of the past, engages the fallacy of affirming the consequences. Thus, discussions of "interests served," like those of "functions performed," characteristically are retrospective in form, reasoning teleologically from selected consequences to presumed motivations (cf. Rock, 1974:598; Hirst, 1972).

A different type of evidence sometimes offered in support of class conflict propositions consists of information on the backgrounds and contacts of persons active in lawmaking. For example, Chambliss (1974:21) regards the fact that "legislatures, appellate court judges, and committee members are drawn largely from upper-class members of society . . ." as evidence of what Schattschneider (1960) calls the "mobilization of bias." However, since the membership of a class itself can be in conflict and since membership in one class need not exclude the possibility of siding with another (Mintz et al., 1976:316, 317), the use of this "guilt by membership" argument often amounts to a genetic fallacy and the tendency to argue *ad hominem*.

Finally, Chambliss and Quinney give little empirical attention to the actual level of conflict, consensus or apathy that may accompany the operation of interests, ignoring that the pursuit of these interests may occur with the explicit or tacit support of those affected (Hopkins, 1975:616). The issue is whether "class interests" operate as causes or whether, in many instances, the association with assumed effects may be spurious.

Where the active pursuit of class interests can be tested for its influence in the presence or absence of consensus, a scientific purpose can be served. It is, however, the recent extension of the Marxian perspective beyond its scientific base that concerns us. Quinney (1973:594) argues that "ideas are to be put at the service of the community . . . , and we ourselves must engage in people's struggles." Our concern is that this ideological mission is

based on a perspective that is (1) prone to logical errors, (2) largely unconfirmed, (3) often unconfirmable and (4) possibly quite frequently false.

The Social History of American Delinquency Legislation

The patterns observed in the development of a Marxist theory of law creation are repeated in Anthony Platt's analysis of the origins of American juvenile delinquency legislation. Platt's original work, *The Child Savers*, is grounded in a theoretical tradition (Ranulf, 1938; Gusfield, 1963; cf. Platt, 1969:3,7) that focused on middle-class interests: "Child-saving may be understood as a crusade which served symbolic and ceremonial functions for native, middle-class Americans" (Platt, 1969:98). The culmination of this "symbolic crusade" was the Illinois Juvenile Court Act of 1899, and Platt adopted a partially pluralist stance in explaining that "its success was due in large measure to the fact that it was *widely* sponsored and in turn satisfied *diverse* interest groups" (1969:134, emphasis added). At this point, Platt's most pressing concerns were that "the juvenile court system . . . 'invented' new categories of youthful deviance . . ." (1969:145), that the child-savers "recommended increased imprisonment . . ." (1969:135), and therefore that " 'delinquents' were increasingly committed to institutions . . ." (1969:145).

Four years later, Platt (1973:26) argues that "ideology is healthy and should be made explicit," and concludes that "the problem with *The Child Savers* is that . . . [it] focuses too much attention on the middle-class reformers. . . ." Platt reasons anew that the impetus for delinquency legislation flowed from close and compromising links between members of the middle and upper classes (1974:369), and that "the juvenile court system was part of a general movement directed towards developing a specialized labor market and industrial discipline under corporate capitalism by creating new programs of adjudication and control . . ." (1974:377).

Evidence for this new, class-interested Marxian theory is the same as that presented in Platt's (1969:ch. 3) original

account and is similar in type to that proposed by Chambliss and Quinney. Descriptions of a "new penology" are offered, but no evidence is provided that passage of juvenile court legislation resulted in an increase in the number of juveniles incarcerated, that the industrial elite benefited significantly as a result of this incarceration, or that the "ruling class" played any direct role in the passage of this legislation. Instead, the primary evidence presented engages a genetic fallacy of the type we previously associated with the "mobilization of bias" argument. Thus, the main body of information consists of a cataloguing of the class backgrounds and backings of persons involved in the child-saving movement. Platt (1969:367-8) concludes that this movement "would not have been capable of achieving significant reforms without the financial and political support of the wealthy and powerful" and that "Even the more radically-minded child-savers came from upper-class backgrounds." What is lacking in this account is any concrete evidence that this sponsorship was a *causal* factor that operated independently of widespread support for the ensuing legislation.

Summarizing, Platt's primary concerns are that links between middle-class reformers and upper-class sponsors resulted in the wealthy and powerful using the passage of American delinquency legislation to "invent" new forms of youthful misbehavior and increase imprisonment, all in the larger interest of "developing a specialized labor market and industrial discipline under corporate capitalism." Alternatively, we have argued that this Marxian perspective on the origins of American delinquency legislation is either unconfirmed or unconfirmable, plagued by logical errors and, therefore, quite possibly false. In the following section, these conclusions are tested anew with historical information on the origins of Canadian delinquency legislation.

The Social History of Canadian Delinquency Legislation

This part of our analysis is based on historical data drawn from a variety of

sources: historical accounts written by participants in, and observers of the child-saving movement; personal correspondence and accounts drawn from the archives of leading advocates of delinquency legislation; proceedings of conferences concerned with child welfare; reports of government commissions; legislative debates; and statistics drawn from the Toronto Juvenile Court. Particular attention is given to an extensive correspondence between the two leading advocates of delinquency legislation in Canada: J.J. Kelso and W.L. Scott.

Our analysis focuses on entrepreneurial interests and activities leading to the emergence of the juvenile court, the organizational development of this court, and the objective consequences of this process (Becker, 1963; Dickson, 1968). Of particular concern is the manner in which the entrepreneurial interests of individuals are aggregated and polarized into organizational issues (Lemert, 1970). Weber reminds us that these organizational issues can be directed to various ends: "bureaucracy as such is a precision instrument which can put itself at the disposal of quite varied—purely political as well as purely economic, or any other sort—of interests . . ." (Gerth and Mills, 1946:231). Thus, Platt's Marxian position is only one among the possibilities entertained by Weber. With this in mind, we will consider first the link proposed by Platt between class interests in social control and the coercive consequence of increased juvenile imprisonment.

Data available for the City of Toronto¹ do not support Platt's position. In the year preceding juvenile court operations, 123 juveniles were sent to industrial schools; 71 were sent to such schools in the first

¹ In the following, emphasis is placed on the development of a system of juvenile justice in Ottawa and Toronto, and the Province of Ontario, as well as on the federal level. Much of the federal legislation was anticipated and first implemented in Ontario, where many of the most influential child-savers lived. As a result of limitations in resources, the provisions of this Act allowed that it not take immediate effect in some cities and provinces, therefore, dates of implementation varied. Toronto was among the first Canadian cities to establish a Juvenile Court in 1912 (Ontario Law Reform Commission, 1974).

year of juvenile court proceedings (City of Toronto, 1912:14). More detailed information on other forms of institutionalization (including a working-boys home, two hospitals and a training school) is available from the court reports of succeeding years (see Appendix 1). Here again, no consistent pattern of increase is apparent, and at no time during the forty-year period does the *total* institutionalized population exceed the number sent to industrial school alone in the year before court operations began.² In the following historical discussion, we will see that the inaccuracy of Platt's position derives from a misrepresentation of legal developments that preceded delinquency legislation in Canada. Furthermore, we will find little evidence, either in personal correspondence or in public documents, that members of the industrial elite expressed an active economic interest in the passage of delinquency legislation. The activities of other individuals and interest groups, particularly those involved with the probation movement (cf. Schultz, 1973), will be considered, but the involvement of the "ruling class" seems to have been peripheral at most. We discuss three periods that preceded the passage of delinquency legislation: an initial period in which lengthy stays in reformatories replaced sentences spent in common gaols; a second period during which treatment-focused industrial schools began to replace reformatories; and a third period when organized probation emerged as a new treatment strategy influential in the development of delinquency legislation.

The child-savers focused first on juveniles convicted as criminals. Two acts were passed in 1857: *An Act for Establishing Prisons for Young Offenders* and *An Act for the More Speedy Trial and Punishment of Young Offenders*. The first directed the construction of "reformatory prisons," while the second provided for summary trial procedures and increased powers to discharge juveniles in order "to avoid the evils of their long imprisonment

previously to trial." Thus, as early as 1857 in Canada, there were provisions for special institutions and trial procedures for juveniles.

In 1874, Ontario passed *An Act Respecting Industrial Schools*, intending to provide residential institutions that would be less severe than reformatories and to which "neglected, uncontrolled, and delinquent" children could be sent. Subsequent to this legislation, J.J. Kelso, a crusading news reporter who later became Ontario's Superintendent of Neglected and Dependent Children, emerged as a key "moral entrepreneur" (cf. Becker, 1963) in the Canadian child-saving movement. In 1887, Kelso brought together the Toronto Humane Society for "better laws, better methods, [and] the development of the humane spirit in all affairs of life" (Kelso, 1911:17; Hodgins, 1888).

Generally consistent with such principles, Ontario passed *An Act for the Protection and Reformation of Neglected Children* in the following year. Provisions of this act allowed that "the Lieutenant-Governor may . . . appoint . . . commissioners . . . to hear and determine complaints against juvenile offenders . . ." and that "their cases be disposed of . . . separately from other offenders. . . ." However, this act also authorized the courts to commit neglected children to industrial schools. Kelso consistently tempered this approach by arguing that "the aim . . . is not to steal children from their parents . . . , but by every available means to make the home and family all it ought to be" (Province of Ontario, 1895). It took Kelso several years to translate these views into law.

In 1890, two additional statutes were enacted in Ontario (*An Act Respecting the Custody of Juvenile Offenders* and *An Act Respecting the Commitment of Persons of Tender Years*), each of which further restricted the use of reformatories and expanded the use of industrial schools for selected children. In 1891, a Commission of Inquiry into the Prison and Reformatory System of Ontario (Province of Ontario, 1891) completed a report that seemed to forecast the shape of things to come. In addition to dealing with institutional reforms, the Commission recom-

² This finding is consistent with less comprehensive figures reported by Scott (1906-1908) for Ottawa and in his correspondence with provincial officials in many other parts of Canada.

mended that magistrates grant discharges to first offenders convicted of trivial offenses and that various powers be given to probation officers.

Later the same year, the Commission's chairman and one of its most prominent members joined Kelso in Toronto to organize a public meeting at which the Children's Aid Society and Fresh Air Fund was founded, with Kelso as President. A letter announcing the goals of this meeting signaled a growing interest in an important organizational innovation: "The appointment of a probation officer to ascertain and submit to the court full particulars of each child brought up for trial, and to act in the capacity of the child's next friend" (see Kelso, 1911:69).

As reform efforts gathered momentum, a theme of professionalism emerged: "What is needed," wrote Kelso (n.d. (a):20), "is personal service, the complete organization of charitable forces, harmony of action, and the appointment of trained and experienced workers. . . ." Gradually, persons involved in the movement seemed to develop an interest in their own positions in an emerging bureaucracy. The influence of this emerging interest group on the legislative process is suggested in Kelso's comment to the Sixth Canadian Conference of Charities and Corrections that "we have as much if not more law than we can assimilate, and the governments are ready to give new measures whenever they are asked to do so . . ." (Proceedings, 1903-1909:21).

The legislation of this period was particularly useful in setting the organizational base for probation work. The first *Criminal Code of Canada* was passed in 1892, providing for separate trials of persons under sixteen where it was "expedient and practicable" to do so; and, in 1893, at the urging of Kelso and others, the Ontario legislature enacted a comprehensive *Children's Protection Act* giving explicit recognition and authority to Children's Aid Societies. The latter act specifically stipulated that it was the duty of the court to notify the Executive Officer of the Children's Aid Society (if one existed in the county) prior to initiating proceedings against a boy under twelve or a girl under thirteen; this officer was then

to investigate the charges, inquire into the child's family environment, and report back to the court with his findings. These procedures were reaffirmed in the following year with a federal *Act Respecting Arrest, Trial and Imprisonment of Youthful Offenders*.

In a short Commons debate of this act, the Minister of Justice and Attorney General noted that "a great many magistrates from motives of humanity" were already conducting separate trials for juveniles (Canada, 1894, June 24:4940-1). A magistrate in the Toronto Police Court later confirmed this, noting that "in 1892 we instituted the Children's Court. . . . We set apart a small room in the lower part of City Hall . . . , and I was accustomed to go down to that room to try all charges against children . . ." (Denison, 1920:254). These developments, and Kelso's role in them, became the basis for claims that the juvenile court had a Toronto origin and was therefore a "Canadian enterprise" that had been appropriated by "American social workers."³ Thus, Kelso later expressed his concern to Scott that "our Ontario work should not be overlooked as I advocated the Children's Court here twenty years ago, gave addresses in Chicago and elsewhere in favor of it and got the law (the Children's Protection Act) passed here in 1893" (Scott, 1906-1908: 12/27/1906; 7/4, 8/1907). One address to which Kelso refers was given in Chicago on October 11, 1893 (Proceedings, 1893; see, also, 1895). Kelso notes that "Judge Hurd consulted with me as to the drafting of the Juvenile Court following my address,"⁴ and that a much discussed extract from this speech appeared in the *Chicago Tribune* the following day (cf. Flexner and Baldwin, 1914:3-4). Kelso's view was that ". . . of course, the Denver

³ For example, these claims are made in a 1933 Toronto newspaper article titled "Juvenile Court had Toronto Origin" (see Hagan, 1977:21). These claims (as contrasted, for example, with those made for New York and Massachusetts) are less important for their factual accuracy than for their indication of close connections between Canadian and American child-saving efforts.

⁴ This comment is found in Kelso's (n.d.(b):19) handwriting at the bottom of a page of an article by Hurly on "The History of the Illinois Juvenile Court Law."

and Chicago courts have far outstripped us but at the same time we gave them the inspiration that led to their present success (Scott, 1906-1908: 12/27/1906).

In 1903, a subsection was added to the Ontario *Children's Protection Act*, specifying that without being convicted of a provincial offense, persons under sixteen could be placed by a judge under the care of a probation officer, who would report periodically "concerning the progress and welfare of the child." The idea of a probation system "to help the children before they become criminally disposed" was increasingly discussed (Kelso, 1907:107). Kelso gave this top priority: "We want to bring about what is called the Probation System, following the children up from their first offense . . ." (Proceedings, 1903:21). The assumption behind this proposal was that imprisonment frequently could be avoided: "Whenever there is an offense there is a cause behind it and our children's court and probation system should be able to reach that cause and . . . remove it for the safety and protection of the children in the home" (Department of Neglected and Dependent Children, 1907:15).

To this point, we have focused on J. J. Kelso as the central "moral entrepreneur" in the advocacy of probation and delinquency legislation. However, he was joined in this pursuit by a "professional" (cf. Becker, 1963:152) counterpart, W.L. Scott, Local Master for the Supreme Court of Ontario and President of the Ottawa Children's Aid Society. Kelso and Scott vocalized three primary concerns. First, additional funds were needed to elevate "philanthropic work to the status of a profession and to encourage University graduates to become specialists in social and moral reform work" (Proceedings, 1907:8). Second, it was claimed that probation officers were now hampered in their work by a lack of "legislative recognition" (Scott, 1906-1908:1/2/1907). And, third, there was a perceived need for special judges: "The Children's Court should undoubtedly be . . . conducted by specially selected persons . . ." (Kelso, 1908:164).

Drafted by Scott and others in response to these concerns, the federal *Juvenile De-*

linquents Act was introduced first in the Speech from the Throne in 1906, reintroduced to the Senate in 1907 and eventually passed in 1908. A "juvenile delinquent" was defined broadly by this act as any child under sixteen who violated any federal or provincial statute, or municipal by-law, or who was liable by any other act to committal to an industrial school or juvenile reformatory. Thus, this act consolidated various previously illegal behaviors into a new category called "delinquency," but it did not add any behaviors to those already specified under existing statutes and by-laws. It would be misleading to conclude, as Platt does for the United States, that Canadian delinquency legislation "'invented' new categories of youthful misbehavior."⁵

The act did, however, give juvenile courts exclusive primary jurisdiction in cases of delinquency. It also provided for the formation of a voluntary Juvenile Court Committee to consult with and advise probation officers, or to appoint an officer where remuneration was available and an officer was not already appointed under provincial authority. Furthermore, probation officers were assigned powers of a constable, with their duties including: conducting investigations, being present and representing the interests of the child

⁵ Sixteen years later, *An Act to Amend the Juvenile Delinquents Act*, 1924, proposed the addition of an omnibus clause—"or who is guilty of sexual immorality or any other form of vice"—to the definition of a juvenile delinquent. However, by this time, such omnibus clauses had been a part of legal definitions of neglect for more than thirty years. It is sometimes argued that such clauses define as delinquent behaviors that are most common among underclass youth. However, this alone cannot count as support for a Marxian class conflict perspective, since the underclass may agree with such legal definitions. The latter possibility is supported by the finding of Black and Reiss (1970) that black complainants are more likely than whites to insist on the arrest of blacks accused of delinquency. Perhaps most significantly, however, the same Marxian theorists (e.g., Liazos, 1974) who claim underclass behaviors are defined differentially by law as delinquent, also cite self-report studies reporting an absence of relationship between social class and delinquent behavior. Probably the safest conclusion is that vague statutory clauses like those defining delinquency depend most heavily for their consequences on the discretion of those who must interpret and enforce them: citizens, the police and prosecutors.

in court, furnishing the court with such assistance and information as required, and taking charge of any child before or after trial, as directed by the court.

Discussions of these and other provisions of the act mainly involved two groups. The ultimately successful group included those who advocated treatment and prevention through probation and a special court; they distributed copies of the bill, circulated petitions, and invited such speakers as Judge Lindsay, of the Denver Juvenile Court, and Mrs. Schoff, of the Philadelphia Mother's Union, to address various gatherings. The opposition included police officers and magistrates who already assumed organizational responsibilities for children and who, therefore, had a very immediate interest to protect (see Scott 1906-1908:3/7, 3/15/1907). This group advocated a more "punitive" approach to delinquency. Particularly vehement in this view were several police officials, including Inspector Archibald and Police Magistrates Denison and Kingsford, associated with the Toronto Children's Court. The debate was often bitter, with Archibald, in a report circulated to gain support for the police position, charging that the new proposals:

work upon the sympathies of philanthropic men and women for the purpose of introducing a jelly-fish and abortive system of law enforcement, whereby the judge or magistrate is expected to come down to the level of the incorrigible street Arab and assume an attitude absolutely repulsive to British subjects. The idea seems to be that by profuse use of slang phraseology he should place himself in a position to kiss and coddle a class of perverts and delinquents who require the most rigid disciplinary and corrective methods to ensure the possibility of their reformation. (Archibald, 1907:5)

In response, Scott (1906-1908:3/19/1907) labeled Archibald a "person of very limited intelligence," while Kelso (Scott 1906-1908:5/14/1907) called him "self-opinionated" and opposed to those who failed to treat him with "deference." Scott (5/2/1907) concluded that the members of the Toronto Police Department felt the new proposals were intended to supplant them and were therefore a reflec-

tion on their past work. Moreover, Archibald's particularly negative attitude was said to be based on the fact that he "had prepared all the legislation on the subject during the last forty years and . . . is apparently deeply offended that anyone else should have usurped this prerogative" (Scott, 1906-1908 4/16/1907).

Scott (1908:894) went on to campaign successfully for the *Juvenile Delinquents Act*, emphasizing in his arguments "that probation is the only effective method for dealing with young offenders." Thus, when the bill was reintroduced to the Senate in May, 1908, Senator Coffey referred to "the difference of view as to the means and methods whereby the best results may be achieved," and explicitly dismissed the position of Inspector Archibald as being characterized by an outmoded "spirit of rigidity and severity" (Canada, 1907-8:975-7). Although some objections were raised in the House of Commons by those concerned with the legal rights of children, the temper of the ensuing debate probably is summarized best by one member of Parliament who observed that the act "is to be laughed through as a joke" (Canada, 1907-8:1240-1). The legislation was passed, but this did not end the organizational search for support. The following years brought a succession of minor revisions and extensions of the original legislation, concerted efforts to secure appropriate provincial legislation creating the newly authorized juvenile courts, and continued efforts to obtain sufficient funds from various levels of government to employ probation officers (Proceedings, 1909; Scott, 1952).

The consequences of the entrepreneurial activities we have described are illustrated in the statistical records of the Toronto Juvenile and Family Court (see Appendix 1). Probation officers in this court predominated in both their number and scale of activities. Thus, while the number of *official* occurrences recorded by the Juvenile Court actually was lower in 1952 than in 1912, during this period the number of probation officers increased from 4 to 14, and the number of occurrences handled *unofficially* by probation officers escalated more than 900 percent, from 735 to 6,574 cases. The Probation

Department apparently did this in a manner the Toronto Police Department seemed initially to fear, that is, by attracting their own new cases and refusing to refer them either to the police or court. Thus, the Probation Department publicly proclaimed that "it is our aim, as far as possible, to settle through the Probation Department all difficulties without making them court cases" (City of Toronto, 1920:5), while also annually advising that "we again, as many times before, earnestly solicit those having problems of various kinds, within the jurisdiction of the Court, coming and allowing us to assist before these problems become too acute so as to require official action" (City of Toronto, 1933:9). Specifically, the Probation Department offered social and clinical investigations in all such cases, leading to dramatic increases in the number of interviews counted annually into the Court Reports. This aspect of the court's work was augmented in 1929 with increased jurisdiction over family matters, followed by increasing rates of court referrals and support actions in succeeding years. In this way, *the social work of the Probation Department steadily increased, without simultaneous increases in the number of adolescents institutionalized or placed on probation*. Thus, in those years when official delinquency actually declined, the Probation Department was quick to observe optimistically "that while we had a decrease in delinquency . . . we had an increase of the numbers who came of their own free will to get help. If it is safe to draw an observation from this fact, it would be reasonable to assume that the non-official effort of the court is reducing its official acts" (City of Toronto, 1933:9). This conclusion was, of course, self-serving; the long term effect on children of this increase in non-official activity remains unclear.

Discussion and Conclusions

The conflict that surrounded the *Juvenile Delinquents Act* in Canada was less about normative definition than about the organizational arrangements under which violators of the norm would be processed. More specifically, it was sup-

porters of the police and advocates of probation who quarreled most about the organizational procedures to be followed. J.J. Kelso, a moral entrepreneur who rose from news reporter to a high position in the child-care bureaucracy, collaborated with W.L. Scott, a professional counterpart and philanthropist who occupied an administrative position in the Ontario Supreme Court, to engineer a legislative movement whose organizational goal became the prevention of delinquency through juvenile probation work. Opposition came from representatives of existing police organizational interests whose more punitive philosophy was reflected in writing prior legislation and their current activities in handling juveniles. Advocates of probation prevailed in the passage of delinquency legislation in 1908, and the consequences of these efforts became apparent in the organizational composition and activities of the new Juvenile Court in Toronto: the handling of *unofficial* occurrences by probation officers dramatically increased, while the level of *official activity* showed some signs of decline.

Whether the eventual success of advocates of probation served the basic interests of the ruling elite is unknown, and probably unknowable, for the various reasons discussed above; however, little influence of the industrial elite was revealed in the personal correspondence and public documents of the key proponents of this legislation. Moreover, in contrast to Platt's account of the passage of delinquency legislation in the United States, no evidence was found in the Canadian data that institutionalization increased as a result of such legislation, or that this legislation was useful in developing a "specialized labor market" or "industrial discipline."

Part of Platt's (1974:389) argument proceeds from a basic Marxian assumption that "as the contradictions (of capitalism) become more apparent and the control system more unsuccessful, the methods of coercion become similarly more explicit and more desperate." It is apparently for this reason that Platt places such great emphasis on the role of the "New Penology" in the emergence of delinquency legislation. In contrast, the argument of

this paper is that it was an emphasis on probation work, and not imprisonment, that led to this new legislation. Thus, although this legislation substantially changed the operations of the juvenile and criminal courts, probably with consequences both good and bad, intended and unintended (cf. Hagan, 1975), the overall effect was not to intensify a formal and explicit system of coercion, but rather to reinforce and increasingly intervene in informal systems of social control, particularly the family. These findings raise the possibility that assumed contradictions in the economic sphere may have only marginal significance for the juvenile justice system, or that these assumed contradictions need not necessarily lead to more explicit methods of social coercion. In any case, this paper provides a considerably different account of the origin of delinquency legislation than is offered by Platt, and it is an account which encourages a reconsideration of the conditions under which this version of a Marxian, class conflict perspective can be usefully applied.

SUBJECTIVE CLASS IDENTIFICATION: A MULTIPLE INDICATOR APPROACH*

JAMES R. KLUEGEL

University of California, Riverside

ROYCE SINGLETON, JR.

College of the Holy Cross

CHARLES E. STARNES

Oregon State University

American Sociological Review 1977, Vol. 42 (August):599-611

Research on subjective class identification has tended to use the same single-item measure of this construct without regard to its validity and reliability. To address these and related measurement issues, multiple indicators of subjective class are analyzed within the framework of a path analytic model with unobservable variables. Measures of objective "class" and political alienation are also included in the construction of an overidentified model, and Jöreskog's procedure for the analysis of covariance structures is used to find an acceptable fit to the data. Final models for black and white subsamples support the assumption of unidimensionality which underlies previous measures of subjective class identification. Validity and reliability estimates are given for various indicators, including the conventional measure. Also, advantages of the multiple indicators approach are demonstrated by comparing regressions of the standard, single-item measure and a composite measure of subjective class on education, occupational status, and income.

Recent research (cf. Hodge and Treiman, 1968; Jackman and Jackman, 1973) on the relationship between objective and subjective placements in the system of social inequality has focused almost entirely upon theoretical issues. The empirical finding that this relationship is far from perfect has tended to be treated as a social fact, and the methodological problems inherent in tests of the relationship have been largely ignored. This is surprising, especially since these same studies have employed research measures which may only crudely approximate the relevant theoretical constructs. In particular, while objective placement has been

consistently treated as multidimensional, subjective placement has been judged *a priori* as unidimensional. Further, there has been no assessment of the validity and reliability of the standard survey question consistently taken as the single indicator of subjective placement. In order to address these measurement issues, we will examine multiple indicators of subjective social class identification within the framework of a structural equation model with latent variables.

Subjective Class Identification

Subjective class identification has been given a variety of meanings. For some it appears to be a substitute for class consciousness (cf. Hodge and Treiman, 1968; Guest, 1974); for others it is treated as

* Authors are listed alphabetically. We wish to thank Eliot Smith and an anonymous reviewer for several helpful comments.

only a component or partial indicator of class consciousness (cf. Morris and Murphy, 1966; Lopreato and Hazelrigg, 1972; Jackman and Jackman, 1973). Little distinction has been made between "class" and "status" consciousness, and class identification often has been used to cover both of these constructs. For example, Jackman and Jackman (1973:569) refer to subjective class identification as "the individual's perception of his own position in the status hierarchy."

Despite differences in conceptualization, the persistent use of the same single-item measure of subjective class identification implies a common assumption of unidimensionality. This consideration alone ought to be sufficient for raising questions about the validity and reliability of the standard measure. But the assumption of unidimensionality not only belies the multiple usages of the term "subjective class," it also seems counter to classical discussions of single versus multiple bases of *objective* class.

Following Weber's (1946) orientation toward the analysis of social inequality, the measurement of objective placement generally has been approached multidimensionally through various socioeconomic indicators. The argument has been made that this approach should be extended to subjective placement. As Morris and Murphy (1966:310) remark, "If Weber's analytical distinctions among class, status, and power have any heuristic significance at all, and the majority of sociologists seem to think they do, then it behooves us to carry out these distinctions in matters of the subjective meaning of stratification."

Taking this consideration into account focuses attention on certain measurement issues. If we consider the possibility that there are different types of subjective identification corresponding to Weber's distinctions between class, status, and power, then we are faced with the question of which of these types the current single-item indicator is measuring. The importance of this question is underscored by the realization that an individual's perceived positions in the three orders may be incongruent. Writing principally in

terms of class consciousness, but with obvious implications for subjective class identification, Lopreato and Hazelrigg (1972:123-5) note:

Weber's taxonomy introduces the distinction of *types*, as opposed to degrees, of social consciousness. There is a type of consciousness corresponding to each of the three orders. The difficulty of treating these phenomena in a single, consistent scheme of analysis stems from the circumstance that, as a society grows in complexity, the likelihood that a given individual will hold an equivalent position in all three orders steadily diminishes. Concomitantly, the likelihood that he will experience his power, prestige, and class position as congruent with one another also diminishes. When we speak of "class" consciousness, therefore, the first question we must raise is, is it *class* consciousness, *status* consciousness, or *power* consciousness? And, further, how are the three interrelated?

Possible incongruence among self-placements ("consciousness") in the different orders raises doubts concerning some of the current interpretations of research findings regarding the relationship between objective and subjective "class." Hodge and Treiman (1968) and Jackman and Jackman (1973), using the same data and the standard single-item class identification measure, found that class identification was only moderately determined by various measures of objective class position. If, however, multiple indicators of self-placement corresponding to Weber's typology were used, then stronger relationships might emerge between analogous dimensions of objective and subjective class. For example, income may be a stronger predictor of subjective class based upon economic criteria than subjective class based upon life-style or influence.

In the remainder of this paper, we examine data pertinent to these issues. A central feature of this data is a group of subjective class identification measures which include, in addition to the standard item, four items intended to correspond to the Weberian distinctions. By construct-

ing a multiple indicator model incorporating these measures, we attempt to determine the dimensionality of subjective class. In addition, an important feature of our approach is that it enables us to assess the degree to which various indicators of subjective class identification are subject to certain types of bias and random errors of measurement.

The Causal Modeling Approach to Measurement Error

Our analysis of the multiple indicators of subjective class identification follows the causal modeling approach to measurement error (cf. Blalock, 1969; Costner, 1969) and involves the application of Jöreskog's (1970; 1971) procedure for the analysis of covariance structures. This approach calls for the construction of hypothesized structural equation models with latent traits to account for the intercorrelations among a set of multiple congeneric measures (or indicators) (Werts and Linn, 1970). A variety of strategies may be applied in arriving at an hypothesized model. The common approach, which we shall use, begins with a model which assumes that measurement error is strictly random. When such a model provides an acceptable fit to the data, coefficients linking latent traits and indicators may be interpreted as validity coefficients and, when squared, as reliabilities (Werts and Linn, 1970; Werts et al., 1974). A comparison of these coefficients then may be used to assess the relative adequacy of the indicators. When the hypothesized model is overidentified, then failure to fit the data may indicate the presence of nonrandom error.

In order to detect certain kinds of nonrandom measurement error involving the subjective class indicators, we construct an overidentified model which includes measures of objective status and political alienation as well as subjective class. These three constructs are all theoretically related. By including an additional latent trait, political alienation, with multiple indicators, we can detect correlated errors and two types of "differential bias" (Costner, 1969).

Data and Method

Data for this research were taken from the 1969 Gary Area Project of the Institute for Social Research at Indiana University. The sample consisted of 800 adults drawn from the city of Gary, Indiana, using a modified probability sample with clusters and quotas (see Sudman, 1966). Trained graduate students and professional interviewers conducted the survey during January, 1969.

The objective status measures were: (a) education—indicated by five categories ranging from less than ninth grade to college graduate; (b) occupation—indicated by two-digit Duncan SEI scores; (c) income—indicated by total family income before taxes in 1967, coded in units of \$2,000 and ranging from under \$2,000 to \$16,000 or more.

All subjective class indicators were structured questions asking respondents to place themselves in one of four class categories: lower, working, middle, or upper. One indicator was a standard, general class identification item; the other four asked respondents to indicate which social class they felt their occupation, income, way of life, and influence were most like. The criteria, in terms of which class self-placements were made, correspond directly to the Weberian dimensions of economic class (occupation and income), status (life-style), and power (influence).

The political alienation indicators consisted of four statements about the national government to which respondents replied on four-point Likert scales. Two of these statements were adapted from Olsen's (1969) Political Incapability/Futility Scale and two were adapted from Neal and Seeman's (1964) Powerlessness Scale.¹

Intercorrelations among the indicators plus their means and standard deviations

¹ These four statements are, respectively: (1) "People like me don't have any say about what the government does." (2) "I don't think public officials care much what people like me think." (3) "The leaders of the federal government don't care what happens to people like me." (4) "This nation is run by the few people in power, and there is not much the little guy can do about it."

are displayed by race in Table 1. Blacks and whites were analyzed separately to control for the possible effects of race.²

Analysis

We assume that the structure of intercorrelations among the twelve measured variables (indicators) can be accounted for by the model in Figure 1. This baseline model (Model I) implicitly assumes that the structure of intercorrelations is completely accounted for by the impact of five latent traits (E, O, I, S, P) on their respective indicators (x_1, x_2, \dots, x_{12})³ and by the correlations among the latent traits. In short, the model assumes that the only errors of measurement are random and that subjective class is unidimensional. Thus, substantively, Model I may be seen as the null hypothesis in testing the alternative that the indicators of subjective class are multidimensional. However, failure to provide an acceptable fit to the data would not necessarily signify multidimensionality but might indicate the presence of nonrandom error.

Before parameter estimates can be meaningfully interpreted, the hypothesized model must provide an acceptable fit to the data. Judgments about the adequacy of the fit are determined by: (a) calculating a χ^2 measure of goodness of fit and (b) observing the residuals matrix, obtained by subtracting the observed correlations (Table 1) from the correlations reproduced by the parameter estimates. The significance of the χ^2 tests the null hypothesis that the observed and reproduced correlations differ within the limits of

chance variation.⁴ Also, the closeness of the χ^2 value to the degrees of freedom is a useful intuitive guide to the adequacy of the fit (Jöreskog, 1971). If the fit is poor, the residuals matrix may be used to draw inferences about how the model should be respecified. Sources of nonrandom error, or invalidity, may then be identified by alternative models which adequately reproduce the matrix of correlations.

By including multiple indicators of more than one latent trait, or unobserved variable, in the model, we can detect nonrandom errors of the following three types (Costner, 1969; Kalleberg, 1974): (1) a direct effect of one trait on indicators of a different trait; (2) an extraneous factor affecting indicators of two or more different traits; (3) a correlation between errors of measurement in indicators of different traits. Where, for example, two unobserved variables are measured by indicators subject to "social desirability" or some other method response set (nonrandom error [2]), a model assuming only random error may consistently underestimate the correlation of indicators across factors. The inclusion of political alienation indicators in the present analysis was based upon the possibility that the similar working of subjective class indicators might imply a response set. Since the alienation items also involve methodological similarities, any common or correlated, method-based response set underlying the two sets of indicators ought to be reflected in the pattern of residuals for Model I.

Maximum likelihood estimates of the parameters of Model I⁵ were obtained through the use of Jöreskog's (1970) general model for the analysis of covariance structures and a corresponding computer program (Jöreskog et al., 1970). Table 2 presents the residual matrices and χ^2 tests

² The decision to examine blacks and whites separately is based upon Jackman and Jackman's (1973) finding of significant race-education and race-occupation interaction effects upon class identification. Among blacks, they found only income to be significantly related to class identification; whereas among whites, class identification was sensitive to education and occupational status, as well as income.

³ Following common practice (cf. Hodge and Treiman, 1968; Jackman and Jackman, 1973), education, occupation, and income have been treated as separate dimensions of objective status, and latent traits corresponding to each dimension have been included in the model.

⁴ Under the assumption of multivariate normality, the test statistic for goodness of fit is distributed as χ^2 with degrees of freedom equal to the number of over-identifying restrictions.

⁵ In estimating model parameters, the values of the paths from each of the objective status latent traits to their respective indicators have been fixed at 1.0. Such a specification is required for purposes of identification and is implicit in analyses with single indicators of constructs.

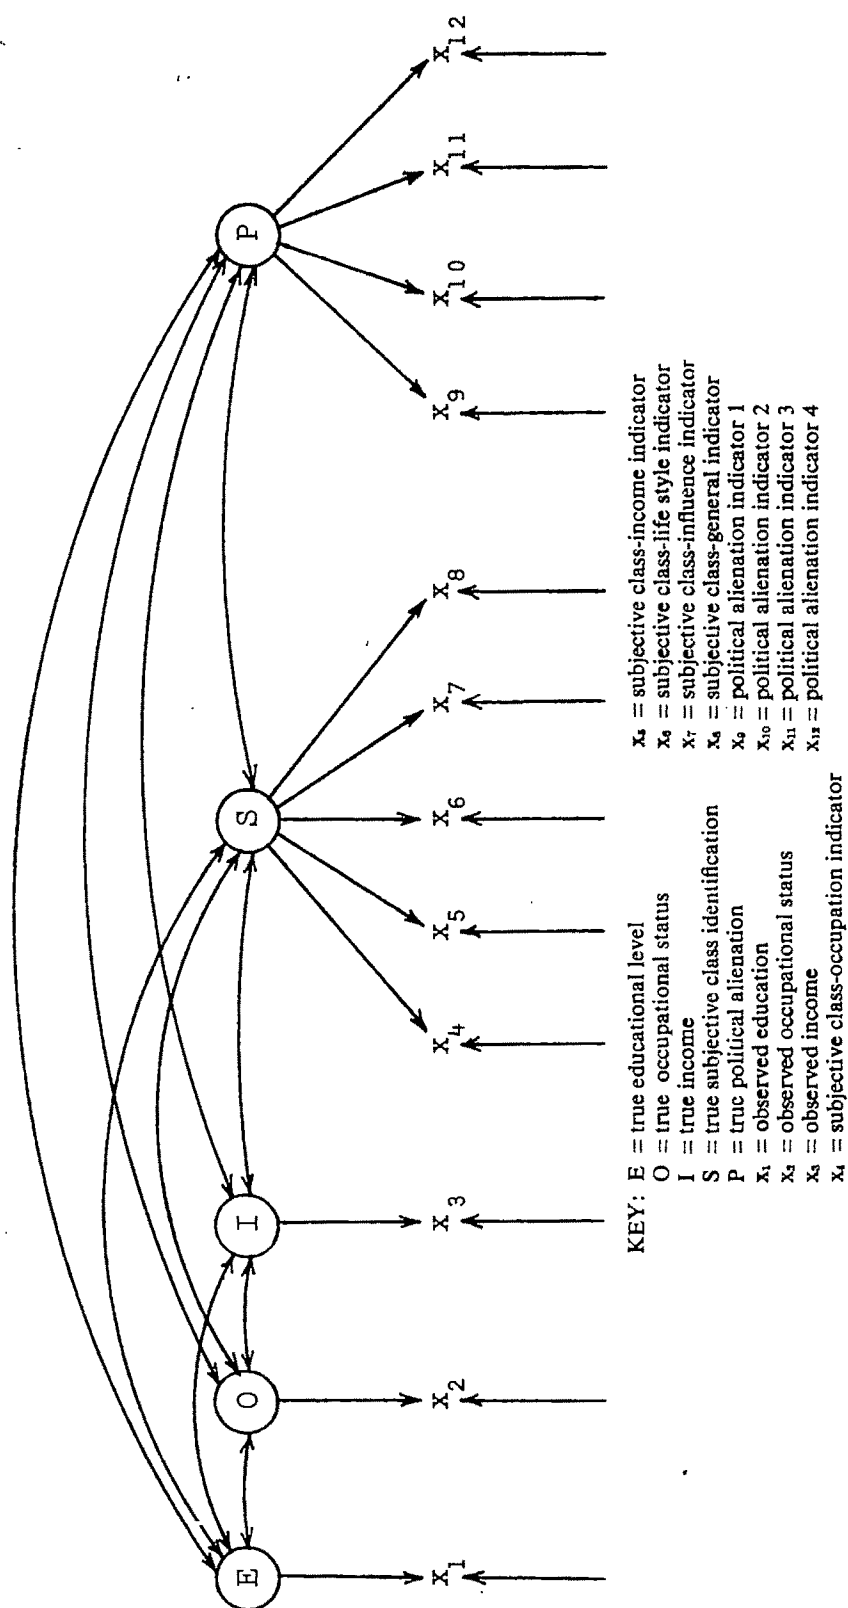

Figure 1. Multiple Indicator Measurement Model (Model I) of Subjective Class Identification

of the Model I estimates for the black and white samples. The χ^2 's indicate a poor fit for both samples. Hence, it is necessary to consider alternative models.

As an initial explanation, we consider the possibility that the poor fit is due to the multidimensionality of subjective class position. Inspection of the pattern of residuals under Model I reveals sizeable discrepancies in the correlations of income (x_3) with the subjective class-income measure (x_6) and of occupation (x_2) with the subjective class-occupation measure (x_4). This suggests an alternative model (Model II) with two separate dimensions of subjective class, one based on income and occupation and the other based on life-style, influence, and general class status. If income and occupational status were more highly correlated with the former dimension than with the later, then the noted deviation in residuals could result.

With 42 degrees of freedom in Model II, the χ^2 for whites = 69.01 ($p = .004$) and for blacks = 85.26 ($p < .001$). Although Model II fits the data better than Model I, as indicated by the reduced χ^2 , the fact that this value is substantially larger than the degrees of freedom indicates that the fit is still inadequate. Further, the hypothesis of multidimensionality loses plausibility in the face of an extremely high correlation between the two hypothesized dimensions of subjective class (for whites, $r = .96$; for blacks, $r = .91$).

On the basis of these findings, we considered various sources of measurement invalidity as explanations for the failure of Model I. An examination of the residuals produced with Model I, plus estimation of models with between-construct (subjective social class and political alienation) error correlations, led to the delineation of the final models (Models IIIa and IIIb) presented in Figures 2a and 2b. Table 3 presents the residuals and χ^2 tests for these respecified models. The χ^2 's indicate a marked improvement in fit in both samples, which leads us to conclude that these models offer an acceptable fit to the observed correlations.⁶

⁶ The decision that Models IIIa and IIIb constitute an acceptable fit (i.e., the decision to stop fitting)

Discussion

As noted above, there are various theoretical reasons for questioning the common practice of treating subjective social class as a unidimensional construct. However, while multidimensional approaches to subjective class have been recommended frequently, empirical research consistently has ignored this issue. A major finding of this study is that a model assuming unidimensionality among a set of indicators of subjective social class provides a better fit to the data than plausible models assuming more than one dimension. Further, although the final models do not fit the data equally well for blacks and whites, this finding holds for both subsamples.⁷ Thus, we have found nothing to disconfirm the assumption of unidimensionality which is presumed by all previous measures of subjective class identification.

Given that subjective class is unidimensional, the various indicators may still be more or less adequate measures of the common factor. That is they may have differential reliabilities and validities as well as being subject to varying sources of nonrandom error. Direct comparison of the indicators of subjective class can be made utilizing the information provided in Figures 2a and 2b. It should be recalled that coefficients linking indicators to the unobserved variable which they are intended to measure may be interpreted as validity estimates and, when squared, as

was made because any further specification would appear to be capitalizing on chance variation. According to Jöreskog (1971:132), the problem of when to stop fitting should be based upon differences between χ^2 values rather than the χ^2 values themselves. If new models yield a reduction in the χ^2 value which is "large compared to the difference in degrees of freedom this is an indication that the changes made in the model represent a real improvement. If, on the other hand, the drop in χ^2 is close to the difference in number of degrees of freedom, this is an indication that the improvement in fit is obtained by 'capitalizing on chance' and the added parameters may not have real significance and meaning." For our data, the drop in χ^2 values would not be large enough to justify the introduction of additional parameters.

⁷ Bielby et al. (1976) have reported a similar difficulty in obtaining equally good fits of measurement models of socioeconomic status measures in nonblack and black samples.

estimated reliabilities.⁸ Comparison of estimated reliabilities and sources of invalidity among the indicators reveals that either the standard general item (x_8) or the item referring to life style (x_9) offers the best single-item measure of subjective social class. Their estimated reliabilities are equally high and no invalidities were detected for either. For blacks, the estimated validity of the standard item is .72; hence, the estimated reliability is .53. For whites, the estimates are .80 and .64, respectively. To our knowledge, these are the first such estimates available in the literature.

Subjective class identifications based upon occupation (x_4) and income (x_5) are the poorest indicators of subjective class, in terms of both their lower estimated reliabilities and their clearly identified sources of invalidity. For blacks and whites, each of these indicators is directly affected by the objective status factor

⁸ It should be noted that our reliability estimates may not apply to other populations. Such generalization assumes that the ratio of true score to error variance is equal across populations. Although it may be reasonable to assume equality of error variance within different populations—since measurement error is often considered to be a property of the measurement instrument (Wiley and Wiley, 1970:112)—it is not always reasonable to assume equality of true score variance across populations. Nor can one assume that increased (or decreased) true score variance will bring a proportional increase (or decrease) in error variance.

The above problem applies to the comparison of estimated reliabilities between corresponding measures from the black and white samples in the present study. The problem may be circumvented, however, by basing comparisons on absolute error variance components rather than standardized coefficients. By fixing one loading of each construct (subjective class and political alienation) at unity and analyzing the variance-covariance matrix of indicators instead of the correlation matrix, the following estimates of error variance components were obtained for the measures of subjective class identification:

	Whites	Blacks
subjective class-occupation	.311	.325
subjective class-income	.269	.376
subjective class-life style	.162	.159
subjective class-influence	.207	.353
subjective class-general	.137	.286

The values of the standardized coefficients can be used legitimately to make comparisons of relative reliabilities within the two samples. However, any comparison of relative reliabilities between samples should be based on the above error variance components and the observed score variances.

upon which the class identification is based (note the paths from 0 to x_4 and from 1 to x_5 in Figures 2a and 2b); and among blacks, the subjective class-occupation item has an additional invalidity due to correlated indicator error across the subjective class and political alienation factors. Apparently, subjects responded to these two items both as questions about class location and as questions about the relative rank of their occupational and income statuses. Also, invalidity in the influence item (x_7), shown in Model IIIb, suggests that blacks may respond to this item on the basis of their perceived political alienation as well as their class placement.

With respect to possible nonrandom errors not detected in the analysis, it should be noted that the pattern of residuals under Model I implies the absence of invalidity due to a generalized response set. Had a common source of variation in the indicators of subjective class and political alienation been present, then a pattern of residuals suggesting the underestimation of correlations between these indicators would have been generated by Model I.

One of the advantages of multiple indicator approaches to measurement is that reliability estimates may be computed and these may be used to correct correlations for attenuation due to random error. In the case of confirmatory factor analysis, the correlations between latent traits represent correlations between "true scores" for the associated constructs (Jöreskog, 1971). In other words, these correlations have been corrected for attenuation due to unreliability of measures. The advantage of the multiple indicator measurement of subjective class over measurement by the standard class identification item may be demonstrated by comparing regressions on the usual measures of objective social class.

For the Gary data, regression of the standard item upon the three objective class measures, education, occupational status, and family income, results in a squared multiple correlation of .079 for the black subsample and .138 for the white subsample. By comparison, a parallel regression for the latent subjective class factor, using multiple indicators, results in

squared multiple correlations of .174 and .189 for blacks and whites, respectively.⁹

Two points are immediately obvious. First, the proportion of subjective class variance explained by the uncorrected regression with the standard item is considerably less than that explained by the corrected regression with measurement by multiple indicators. Since it has been common practice to use the standard class identification item without regard to its reliability, this suggests that prior findings underestimate the degree to which objective and subjective class may be related.¹⁰ Second, however, even with the improved reliability of the composite measure, the relationship between objective and subjective class remains weak. While prior research may have underestimated the relationship by virtue of ignoring unreliability and employing a single indicator, it appears unlikely that increased reliability via multiple indicators will produce a high observed correlation between objective and subjective class. By and large, it remains for theory and substantive research to explain the large residual.

Conclusion

Subjective social class identification has been a central concept in much of the theory and research on social stratification but, in spite of its importance, little attention has been paid to the adequacy of its measurement. By formulating a multiple indicator model, we have been able to

address certain key issues in the measurement of subjective class. Although there are theoretical reasons to question the validity of the conventional single-item measure, our analysis shows that this measure fares quite well in comparison to other plausible indicators. However, as we have demonstrated, the reliability of the conventional measure can be improved by constructing a composite measure.

⁹ The unstandardized regression coefficients for whites are: Single Item (x_0): Subjective Class = $.119x_1 + .002x_2 + .047x_3$; Latent Subjective Class Factor: Subjective Class = $.110x_1 + .001x_2 + .052x_3$.

The unstandardized regression coefficients for blacks are: Single Item (x_0): Subjective Class = $.092x_1 + .002x_2 + .072x_3$; Latent Subjective Class Factor: Subjective Class = $.070x_1 + .006x_2 + .097x_3$.

¹⁰ The squared multiple correlations (SMCs) in our data, using the conventional measure, are considerably lower than that found by Jackman and Jackman (1973:574) in the 1964 NORC general survey. We suspect that the lower SMC we obtained for the standard measure is due to the nature of our sample, which is restricted to a single urban, highly industrialized city. It seems likely, therefore, that the use of multiple indicators to measure subjective class in a national sample would result in similar increases in the SMC over the single indicator without correction for attenuation.

DEMOCRACY AND SOCIAL INEQUALITY: A REANALYSIS*

RICHARD RUBINSON AND DAN QUINLAN

*The Johns Hopkins University**American Sociological Review* 1977, Vol. 42 (August):611-623

Papers by Cutright and Jackman test the hypothesis that democratization reduces inequality in national societies. Cutright finds a negative effect of democratization on inequality, while Jackman finds no effect. In this paper, we reanalyze and extend these analyses. We consider five issues and our findings are the following: (1) the two different indexes of democratization used are not the likely cause of the discrepant findings; (2) the different samples are not the likely cause; (3) the probable cause of the different results seems to be in the data used or coding procedures that Cutright and Jackman employed in constructing their measure of sectoral income inequality; (4) substituting personal income for sectoral income in the analysis, we find that both the Cutright and Jackman indexes have negative effects on inequality; (5) we test the alternative specification which hypothesizes that inequality has a negative effect on democratization, and then test these two different hypotheses. This analysis supports the hypothesis that inequality has a negative effect on democratization, but there is less empirical support for the original hypothesis that democratization negatively affects inequality.

In a recent paper, Jackman (1974) addressed the issue of the relationship between political democracy and social inequality. Jackman's analysis was based on an hypothesis of Lenski (1966) which argued that the rise of democracy was one of the reasons for the decline of the degree of inequality in industrial societies relative to agrarian societies. Jackman's empirical analysis compared the Lenski hypothesis that political democracy reduces inequality with an alternative hypothesis that the relationship of democracy to inequality is spurious, once the level of a country's economic development is controlled. His

empirical results supported the hypothesis of a spurious relationship between democracy and inequality. These results, however, contradict the findings of an earlier study by Cutright (1967). Cutright investigated the same set of relations, and his empirical results showed that there was a significant negative effect of democracy on inequality, even controlling for the level of economic development. Thus, two similar studies investigating the same hypothesis reach different conclusions. Because the relationships among the three variables of democracy, inequality and economic development are of continuing concern in comparative politics (Banks, 1972; Cnudde, 1972; Lipset, 1960; Moul, 1974), it is important to reanalyze these findings.

Cutright's study explicitly tested the hypothesis that political democracy re-

* This research was supported in part by the National Science Foundation, Grant GS-23065. We wish to thank Chris Chase-Dunn, Howard Nixon, Rafe Stolzenberg and Rick Tardanico for their assistance on this research.

duces inequality in nations. He tested this hypothesis through a cross-sectional regression analysis, using a sample of 52 nations. Inequality was measured by the Gini index of *sectoral* income inequality, and democracy was measured by the political representation index (PRI) developed by Cutright (1963). Economic development was measured by an economic development index (EDI). Cutright (1967) used a stepwise regression procedure in which the economic development index was introduced first and then followed by the measure of democracy, PRI. He found that democracy exerted an independent negative effect on sectoral income inequality.¹ He concluded that political democracy does reduce inequality, a finding that he interpreted as supporting the Lenski hypothesis.

Jackman's (1974) analysis also tested this hypothesis through a cross-sectional regression analysis, using a sample of 60 nations. He used three indicators of social equality, the Schutz coefficient of *sectoral* income inequality, SIPE and a social welfare index.² He measured democracy by an index of democratic performance (DP). Jackman performed three separate regression analyses in which each indicator of social equality was regressed on the ln-energy consumption per capita (KWH) and the index of democratic performance. In all three regressions, the measure of democracy had no significant effect on the indicators of social equality.³ From these results, Jackman concluded that there was no independent effect of democratization on inequality.

¹ The stepwise regression procedure performed by Cutright could only have underestimated the effect of PRI, since this index of democracy was entered after the economic development index.

² While Cutright summarized sectoral income distribution by the Gini coefficient and Jackman summarized this distribution by the Schutz coefficient, these different summary coefficients cannot account for the discrepant findings since Jackman (1975:17) reports that Alker and Russett found that the two coefficients, if computed from the same distributions, correlate at .95.

³ The fact that Jackman used kilowatt-hours of electricity consumed and Cutright, at times, used an economic development index does not seem to be a source of the discrepant findings, since such various measures of economic development all tend to correlate very highly.

In trying to understand these divergent findings, we focus on four issues raised by these analyses: the different indexes of democratization used, the different samples of countries used, the relationship between sectoral and personal income inequality, and the important issue of the direction of the causal relationship between democratization and inequality.

We also should point out that Cutright and Jackman have extracted only one very small hypothesis from the very rich and complex theoretical model developed by Lenski. Their results and those we will report therefore should not be interpreted as confirming or disconfirming Lenski's theoretical model.

Comparison of the Measures of Democratization

In discussing the fact that his results do not agree with those of Cutright, Jackman focuses on the issue of the measurement validity of the indexes of democratization. Jackman argues that his index of democratic performance more accurately measures what most theories mean by democracy because it emphasizes political participation and freedom of competition. Cutright's index, he argues, measures political stability more than democracy because of its emphasis on the existence of parliamentary forms of government (Jackman, 1974:43).

The operational procedures used in constructing the two measures are, in fact, quite different. Jackman's index consists of four items of (1) the ratio of the number of adults voting to the total voting age population, (2) the competitiveness of the party voting system as coded by Rummel (1966), (3) the degree of press freedom as presented in Taylor and Hudson (1972) and (4) the degree of electoral irregularity as presented in Taylor and Hudson. These four components were equally weighted and summed to give the score on democratic performance. Cutright's (1963:256) political representation index is constructed in the following way: a nation is given a score of two points for each year that "a parliament existed in which the lower or the only chamber contained representatives of two or more political

parties and the minority party or parties had at least 30% of the seats." One point was given to those countries that complied with the above criteria but lacked the 30% criterion. Nations for that year that had no parliament or had the parliament abolished by executive fiat received no points. Countries received an additional point if the chief executive was in power by virtue of a direct vote or was selected by the party in power in parliament, if the parliament satisfied the above two criteria. One-half point was given to nations that selected their chief executive by other means, but no additional points were given if the nation was ruled by an hereditary ruler or a foreign power. The index consisted of the total points for each year from 1945-1954. Thus, in contrast to Jackman's, Cutright's index stresses the formal structure of the regime and its stability, and it is for these reasons that Jackman asserts that his measure is a more valid measure of democratization while Cutright's is a measure of stability.

While there have been critiques of the conceptualization and operationalization of indicators of democratization (Burrowes, 1972; Moul, 1974), our concern here is with a more narrow question: Do these two indexes measure different aspects of a nation's political structure, as Jackman claims, or are they empirically indistinguishable? In order to answer this question, we inspected the correlation matrix and performed a factor analysis of these two indexes and a third index of democratization, Dahl's (1971) polyarchy measure. We included this third index because Jackman states that his measure of democratization is conceptually similar to Dahl's polyarchy measure (Jackman, 1975:64). Two different samples of countries were used in this analysis—the first sample ($N=47$) consisting of all nations which have scores on all three indexes of democratization, and the second sample ($N=32$) consisting of countries which have scores on the democracy indicators and have data on personal income distribution.⁴

⁴ The scoring for Jackman's Democratic Performance (DP) index is taken directly from Jackman (1975:216-8). Cutright's Political Representation Index (PRI) is coded as five-year averages, for the

We found that the correlations among the three indicators of democratization are all relatively high. In the larger sample, the correlation between the Jackman and Cutright indexes is .8182; and both of these indexes have essentially the same correlation with Dahl's index, .7201 for Jackman and .7330 for Cutright. In the smaller sample, the correlation between the Jackman and Cutright indexes is .6783; and the two correlate at .6063 and .6038, respectively, with Dahl's index. The relatively high magnitude of these correlations implies, to some extent, that it is not possible to simply assert (as does Jackman) that the different effects found by Jackman and Cutright are explained by the fact that the two indexes measure different political dimensions.

In the factor analyses, a principal factor solution was applied to the correlation matrix of indicators (Van de Geer, 1971:128-55). A strong indication that the three measures of democratization are empirically indistinguishable would be if the first factor to emerge were to account for a disproportionately large share of the variance of the three measures and the two subsequent factors accounted for a relatively small share of the variance. This is what we found. In the first sample of 47 nations, the first factor to emerge accounted for 83.8% of the variance in the democratization indexes; the second factor accounted for 10.1% of the variance; and the third factor accounted for 6% of the variance. The eigenvalue for the first factor was 2.282. Further, the factor loadings on this factor are all quite similar. Cutright's measure has the highest loading, .9118; Jackman's measure has the next highest loading, .8967; and Dahl's measure has the lowest loading, .8038.⁵

five years closest to the income inequality measure which will be discussed later.

⁵ The lower loading of the Dahl polyarchy index is probably due to the fact that we could not use Dahl's full two-dimensional measure because we knew of no way to weight the two dimensions (which Dahl presents separately) and combine them into one index. We used only the dimension of the "degree of competitiveness of a nation's political system," and did not use his dimension of inclusion, the extent to which all citizens are included in the political process. For this reason we do not include Dahl's index in later analyses.

The smaller sample showed essentially the same pattern of results.

In both samples, the first factor accounts for very substantial proportions of the variance and the subsequent factors account for very little of the variance. Also, the loadings of the indexes are quite consistent across the two samples. These results cast doubt upon the assertion that these measures of democratization are capturing distinctly different dimensions of a nation's political structure and that this is the reason for the different findings of Jackman and Cutright. Rather, these results cast doubt on Jackman's claim that the difference between his findings and Cutright's findings are due solely to the fact that their indexes of democratization are empirically measuring different dimensions of political structure.⁶

Comparison of the Samples and of Sectoral Income Inequality

A second reason why the two studies reach different conclusions may arise from different samples. Both Jackman and Cutright used only those countries for which there was complete data on their various indicators. Jackman's sample had 60 countries, while Cutright's sample had 52 countries. However, comparing the samples shows that they had 44 cases in common. Since Jackman's index of democratic performance was constructed from secondary sources, it is impossible to create identical samples. We suspect that because of the high proportion of common cases the different samples alone cannot explain the discrepant findings.

However, another factor which may explain the discrepant findings did appear. This factor concerns the measures of sectoral income inequality. Both Jackman and Cutright used sectoral income in-

equality as a measure of inequality. Cutright constructed his sectoral income measures himself, while Jackman took his sectoral income measure from Taylor and Hudson (1972). While they both used the same conceptualization of sectoral income inequality, it is possible that errors resulting from coding or from using different sources for determining sector income and workers per sector could be responsible for the discrepant findings. The two scorings of sectoral income inequality obviously should correlate very highly.⁷ When we correlated the two measures for the 44 common cases, however, we obtained a correlation of only .645. Although we cannot determine exactly the source of this low correlation, we can conclude that the difference in findings between Cutright and Jackman may be due to the fact that the two measures of sectoral income inequality do not correlate highly.⁸

Reanalysis Using Personal Income Distribution

If the difference in the findings is due to differences in the scoring of sectoral income inequality, we still cannot determine which result is correct. Both Jackman and Cutright assert, however, that sectoral income inequality is not as good a measure of social inequality as is actual personal income distribution (Cutright, 1967:563; Jackman, 1975:19-21). Both Jackman and Cutright were forced to use this measure because they did not have measures of personal income distribution. Sectoral income inequality is a measure originally developed by Kuznets (1963). It is computed by dividing the per-

⁷ See footnote 2.

⁶ Strictly speaking, without more analysis, we cannot conclude that because the correlations among these indexes can be reproduced by a common factor that these variables are measuring the same dimension, since the variables may be spuriously related. However, our aim is merely to show that the Jackman and Cutright indexes are so empirically interrelated that the difference between them is not sufficient to account for the different empirical results in their studies.

⁸ Another factor that could produce different results stems from the fact that the two studies used somewhat different time periods. Cutright's study seems to pertain to the mid-1950s, while Jackman's study seems to pertain to the mid-1960s. We say "seems to" because it is not possible to ascertain from the sources exactly what are the actual time periods for the data. And, in fact, Jackman (1974:33) notes that he uses some data from Cutright's original study. Our analyses in the next section, however, show that both Jackman's and Cutright's democratization indexes have the same effects on personal income distribution, so we feel that the somewhat different time periods are not causing the problem.

centage of total domestic product produced in eight economic sectors (agriculture, mining, manufacturing, etc.) by the number of workers in each sector. While this computation only gives the distribution of per worker product across economic sectors, both Cutright and Jackman use it as a proxy for personal income. Using sectoral income for this purpose, however, assumes that the income within each production sector is equally distributed among all economic actors within the sector. This assumption is unrealistic (Husbands and Money, 1970). A better test of the Lenski hypothesis of the effect of democratization on inequality is to use personal rather than sectoral income inequality. To do this, we take income distribution data from Paukert (1973), who presents data showing the share of pre-tax personal income accruing to the five quintiles of households in 56 countries. We use this data to reanalyze the relationship between democratization and inequality.⁹

To test the hypothesized relationship using the Gini index of *personal income inequality* (computed by Paukert, 1973) as the dependent variable, we use the exact functional form of the regression equation used by Jackman:

$$Y_1 = a + b_1X_1 + b_2X_2 + e \quad (1)$$

where: Y_1 = Gini index of personal income inequality

X_1 = Jackman or Cutright democracy index

X_2 = ln kilowatt-hours of energy per capita (KWH).

The results from the estimation of equation (1), with t-scores in parentheses, are:

$$\begin{array}{ll} \text{Gini Index} = .0003 \text{ KWH} - .033 \text{ Jackman}^* & \\ \quad (.237) & (2.39) \\ R^2 = .188, N = 32 & \end{array}$$

$$\begin{array}{ll} \text{Gini Index} = .0005 \text{ KWH} - .006 \text{ Cutright}^* & \\ \quad (.434) & (1.88) \\ R^2 = .155, N = 32. & \end{array}$$

These results show that the effect of Jackman on the Gini index of personal income inequality is $-.033$, with a significant t-statistic of 2.39.¹⁰ Other results, not presented here, also show that Jackman has significant effects on increasing the income of the bottom 20% of the population and the middle 40–60% and decreasing the relative share of the income of the top 20% of the population. Thus, when we substitute personal income as the measure of social inequality, a measure that Jackman himself claims is superior to his own, we find that his indicator of democratic performance does have significant effects on reducing income inequality, even controlling for the level of economic development.¹¹

These results also show that the effect of Cutright on the Gini index is $-.006$, with a significant t-statistic of 1.88. Other results, not presented here, also show that Cutright has a significant positive effect on the share of income occurring to the bottom 20% of the population and a significant negative effect on the share of income of the top 20% of the population. Thus, these results parallel those using Jackman's measure of democracy. They show that Cutright's political representation index has significant negative effects on personal income inequality.

From this reanalysis, we can conclude that the two indicators of democratization both have negative effects on social inequality. These results tend to support our earlier analyses which showed that both indicators of democracy were empirically very similar. At this point, the analysis seems to support the hypothesis that democratization has a negative effect on inequality.

⁹ Our data for personal income distribution are for different time periods, with most of the data being from the mid-1960s. Therefore, we matched the other variables to the exact year of the income inequality data. Cutright's index was constructed as five-year averages for the five years closest to the income inequality measure. Kilowatt-hours was coded for the exact year of the inequality measure. Since Jackman's index cannot be replicated (as can Cutright's we had to use the original scores presented by Jackman (1975).

¹⁰ We use a significance level of .05 indicated by an asterisk (*) with a one-tailed test throughout the paper.

¹¹ The number of cases for which we could get data on personal income inequality, kilowatt-hours, and the Jackman and Cutright indexes is 32. Though this number is smaller than that used in the other studies, the results from this and subsequent analyses are so consistent that we have confidence in the findings.

An Alternative Specification

If we were to end the analysis at this point, we would conclude that political democracy does have a significant negative effect on inequality. However, we now consider an issue which was not addressed by either Jackman or Cutright, the issue of alternative specifications. Both Jackman and Cutright model the relationship between democracy and inequality as a one-way causal relationship in which democracy affects inequality. Neither entertains the possibility that inequality affects democracy.

Although neither Jackman nor Cutright discuss this alternative causal ordering, there is a large body of research which leads to the implication that inequality has an important effect on democratization. The reasoning behind such an assertion is the following. Observation of inter-country differences in income inequality shows that most of the variation occurs in the middle of the income distribution. The countries which exhibit the greatest income *equality* are those which have a greater share of income going to the third and fourth quintiles of the population and a smaller share of income going to the top 20% of the population. Countries with the most unequal income distributions are those in which the top 20% of the population has a relatively large share of the income and the middle quintiles have a relatively small share (Paukert, 1973). That is, the empirical evidence shows that inter-country differences in inequality are largely a function of the relative strength of the middle-class groups in a country. These observations lead to the conclusion that the shape of the income distribution is primarily a function of the relative strength of economic groups in a country, with the lowest amount of inequality being associated with large and economically powerful middle-class groups. Thus, when we compare countries on inequality, basically we are comparing their class structures and, particularly, the degree to which they are dominated by a middle class. It is interpreting inequality as an indicator of class structure that leads to the hypothesis that social inequality affects democratization.

There are a number of historical studies which point to the hypothesis that the class structure of a country has an important effect on democratization. Such a perspective immediately suggests Marx's analysis which argued that the rise and institutionalization of the bourgeoisie lay behind the shift to parliamentary democracy in European countries. This relationship between the bourgeoisie and democratization arose because the rising capitalist classes used parliamentary mechanisms to wrest control of the state from the Crown and the traditional landed elite (Marx, 1926). Similarly, Moore (1966:413-32), in his famous study of political regimes, argues that the urban bourgeoisie has been the crucial group in the major democratic revolutions. It is the existence of a strong and organized urban bourgeoisie, he concludes, which has been the necessary condition for the institutionalization of democratic forms of government. Soboul (1975), in his analysis of the French Revolution, emphasizes that the triumph of legal equality (the classic conception of democracy) over other visions of equality was established by the eventual control of the French state by the urban bourgeoisie.

Such studies lead to the implication that the degree of social inequality, because it is an indicator of class structure, affects democratization. This hypothesis can be tested by estimating equation (2) below. Economic development also is included in this equation as one of the determinants of democratization (Cutright, 1963; Jackman, 1975; Neubauer, 1967).

$$X_1 = a + b_1 Y_1 + b_2 X_2 + e \quad (2)$$

where: X_1 = Jackman or Cutright democracy index

Y_1 = personal income inequality, Gini index or 3rd Quintile

X_2 = 1n kilowatt-hours of energy consumption per capita (KWH).

This equation differs from equation (1) because the causal relationship between democracy and inequality is reversed. Besides presenting the effects of the Gini index on democratization, we also present the effects of the 3rd quintile (the middle

40–60%) of the population here because it represents the proportion of income which accrues to the middle of the income distribution and, thus, is one indicator of the economic strength of the middle-class groups in the countries. According to the works cited above, we expect that this variable should have *positive* effects on democratization and that the Gini index should have *negative* effects. While it is not necessary that the larger the income share going to the 3rd quintile, the less the inequality, it is empirically true in the data on income distribution presented by Paukert (1973) and analyzed by Robinson (1976). For example, the correlation between the relative proportion of income accruing to the 3rd quintile and the Gini index is $-.889$ in the sample including Cutright, and this correlation is $-.875$ in the sample including Jackman. The results from the estimation of equation (2), using the two indexes of democratization and the two measures of inequality, are presented below with the t-scores in parentheses:

$$\text{Jackman} = .035\text{KWH}^* - 56.41 \text{ Gini index}^* \\ (2.65) \quad (2.39)$$

$$R^2 = .345, N = 32$$

$$\text{Cutright} = .024\text{KWH}^* - 17.11 \text{ Gini index}^* \\ (5.45) \quad (1.88)$$

$$R^2 = .580, N = 32$$

$$\text{Jackman} = .023\text{KWH} + 2.08 \text{ Quintile 3}^* \\ (1.68) \quad (3.08)$$

$$R^2 = .409, N = 32$$

$$\text{Cutright} = .022\text{KWH}^* + .529 \text{ Quintile 3}^* \\ (4.49) \quad (1.94)$$

$$R^2 = .583, N = 32.$$

The results of these equations show that the Gini index has significant negative effects on both the Jackman and Cutright indexes of democratization. These results also show that there are significant positive effects of the 3rd quintile on both these measures of democratization. Both sets of results are consistent with the hypothesis outlined above.

The results from equation (1) support the hypothesis that democratization has a significant negative effect on inequality, and the results from equation (2) support the alternative specification that inequality has a significant negative effect on democratization. These results, however,

arise from the independent estimation of each equation by ordinary least squares (OLS), and therefore it is difficult to determine the relative validity of each specification. It seems reasonable now to attempt to make a preliminary determination about the relative validity of each specification by testing a model which allows for reciprocal effects between democratization and inequality. Since in their present form equations (1) and (2) cannot be estimated by OLS, we will estimate this system of equations through the method of instrumental variables (IV).

Before proceeding with the instrumental variables analyses, we caution the reader on two issues. First, our analysis is intended to be exploratory. We have found that there is theoretical and empirical support both for the assertion that democratization affects inequality and for the assertion that inequality (interpreted as class structure) affects democratization. The empirical cross-national research that we have been discussing has concentrated exclusively on evaluating the first assertion. We have shown, using the same type of data, sample and methods, that there is equal support for the second assertion. It seems necessary, therefore, to begin to make some assessment of the relative merits of each assertion, since the issues raised here are central for the development of an adequate model of the relationships between economic and political structure. Our analysis, therefore, should be seen as only a first step in this task, and our results should be considered tentative until there is much more research on this issue.

Second, we alert the reader to the complicated issue of the choice of instrumental variables. The two requirements for an instrumental variable are that it is uncorrelated with the error in the equation and that it is correlated with the regressor (Wonnacott and Wonnacott, 1970:159). Given these requirements, a very large range of variables may be acceptable, even variables which are not theoretically relevant. Consequently, it is often stated as a "conservative" guide that instruments should be chosen from within a fully developed structural model (Wonnacott and Wonnacott, 1970:160). Unfor-

tunately, such a model has yet to be developed for the interrelationships we are studying. Our analysis, in fact, is one part of an attempt to develop such a model. We proceed, then, to construct a slightly larger model in which we add one theoretically relevant variable to each equation.

Two variables, an index of Horizontal Power Distribution (POWCON) and government revenue as a percentage of gross domestic product (GOVREV) will be added to the model. If we refer to GOVREV as X_3 and POWCON as X_4 , and retain the symbols used previously for the remaining variables, the specification of the model is:

$$Y_1 = a_1 + b_1X_1 + b_2X_2 + b_3X_3 + e_1 \quad (3)$$

$$X_1 = a_2 + b_4Y_1 + b_5X_2 + b_6X_4 + e_2. \quad (4)$$

This model produces a just-identified system of equations that satisfies the assumption that the errors are uncorrelated with the independent variables in the equations when the system is estimated by the method of instrumental variables (Wonnacott and Wonnacott, 1970:152-63).¹²

The Horizontal Power Distribution index (POWCON), created by Banks and Textor (1963:106), measures the degree to which the different branches of govern-

ment (whatever they may be) exercise the functions normally attributed to them, or whether they are dominated by another branch of government or extra-governmental agency. This variable is scored 0, 1 and 2, with 0 representing a more equal power distribution among governmental branches and 2 representing a more unequal or concentrated power distribution. The Horizontal Power Distribution index captures the idea of countervailing governmental power or "checks and balances" which is so often postulated to be a necessary condition for democratization (Dahl, 1971; Lipset, 1960). According to our perspective, it provides the institutional conditions that allow societal competition to be politically organized and legitimated within the government. Therefore, we expect that this variable will have a negative relationship to the measures of democratization, and that horizontal power distribution does not directly affect a society's class structure.

Our reasoning for including government revenue as a percentage of gross domestic product in equation (3) is that government revenue is a measure of state strength, and the strength of the state is one of the most important causes of inter-country variations in class formation and inequality (Wallerstein, 1972). State strength has this effect because the state is one of the primary mechanisms for controlling the world-economy to the advantage and disadvantage of various economic groups. We expect that state strength only affects democratization through its effects on a society's class structure. A fully developed explanation for these assertions is presented in Robinson (1976). We expect that this variable will have negative effects on the Gini index and positive effects on the share of income accruing to the 3rd quintile. Government revenue has been coded from the International Financial Statistics Supplement (IMF, 1972).

The results of the instrumental variables estimation are presented in Tables 1 and 2 under columns 2 and 4. The OLS estimates of the same equations are presented for comparison in columns 1 and 3 of these tables. Column 2 of these tables shows the regression estimates of

¹² One way to state the statistical requirements for the instruments is to see if they are correlated with the regressor and have no statistically significant direct effect on the dependent variable when the other relevant variables are controlled (Namboodiri et al., 1975:552-5; Heise, 1975:160-5). In the sample using the Jackman index, the correlation of POWCON and Jackman is -.556, and the correlations between GOVREV and the Gini index and the 3rd quintile are -.297 and .436. In the sample using the Cutright index, the correlation of POWCON and Cutright is -.802 and the correlations between GOVREV and the Gini index and the 3rd quintile are -.387 and .523. We then ran eight OLS equations in which we regressed the two measures of inequality on the two measures of democratization, KWH, and POWCON, and in which we regressed the two measures of democratization on the two measures of inequality, KWH, and GOVREV. In seven of the eight equations, there was no significant effect of the instruments on the dependent variable. Only in the case of the equation with the 3rd quintile with Jackman was there such an effect. However, because of the consistency of the results in the eight sections on the IV analysis, this is not too problematic. Because of these tests we feel that POWCON and GOVREV are adequate instruments.

Table 1. Analysis Using Jackman's Index: Ordinary Least Squares (OLS) and Instrumental Variables (IV) Regression Estimates

Variables	(1)	(2)	(3)	(4)

the effects of democratization in inequality, the regression estimates of the effects of inequality on democratization are shown in column 4. The comparisons among these coefficients represent the main focus of interest in these analyses. Before discussing these results, however, we briefly consider the other effects in these tables.

First, we see that the instrumental variables operate as expected. POWCON has significant negative effects in all equations. GOVREV has its expected negative effects on the Gini index and its expected positive effects on the 3rd quintile. These effects are statistically significant for the IV solution (in column 2) except for its effect on the 3rd quintile in Table 2. We also see that there is no statistically sig-

nificant effect of KWH on the Gini index or on the 3rd quintile. (Recall that there was also no effect of KWH in the previous analysis of equation [2].) While these results may seem surprising to some, they are not unique to this analysis. Robinson (1976), in a larger sample of countries, found that there was no significant effect of KWH on the Gini index when GOVREV was controlled. Jackman (1975:196) also found that there was no statistically significant effect of KWH on the Schutz index of *sectoral* income inequality when civilian government expenditures (a measure similar to GOVREV) was controlled. Thus, these effects in Tables 1 and 2 correspond to other sets of findings.

We now consider the effects between the indicators of democratization and in-

Table 2. Analysis Using Cutright's Index: Ordinary Least Squares (OLS) and Instrumental Variables (IV) Regression Estimates

t-statistics in parentheses.

equality. Inspecting the upper half of Table 2, column 1, we see that Jackman has an effect of .017 on the Gini index, with a nonsignificant t-statistic of .450. Comparing this effect with the estimate from the OLS model (-.042, with a significant t-statistic of 2.03), we see that IV estimation changes the sign of the coefficient from its hypothesized negative to positive and, also, changes the size of the coefficient from -.042 to .017. Column 4 shows that the effect of the Gini index on Jackman is -143.35, with a significant t-statistic of 2.34. Comparing this effect with the estimate from the OLS model (-60.741, with a significant t-statistic of 2.90), we see that the IV estimation has increased the size of this coefficient by 136%, while retaining its hypothesized

negative sign. Inspection of the standard errors for these variables (not reported in the table) reveals that the changes in statistical significance are not just a function of differences in the inflation of standard errors, which is often a consequence of the IV solution. The standard errors of Jackman and the Gini index both double in size. From this half of Table 1, then, we see that the instrumental variables estimation increases the size of the negative effects of the Gini index on Jackman and changes the sign of the effect of Jackman on the Gini index from the expected negative to positive.

Inspecting the bottom half of Table 1, we see the same pattern of results. In Column 2, the effect of Jackman on the 3rd quintile is -.082, with a nonsignificant

t-statistic of .703. While the IV estimation has changed the size of this coefficient from the OLS estimate (.110, with a significant t-statistic of 2.69), it is again the wrong sign for the hypothesis. In column 4, we see that the effect of the 3rd quintile on Jackman is 4.03, with a significant t-statistic of 2.62. The size of this coefficient is 75% greater than the OLS estimate, and it retains its hypothesized positive effect. Inspection of the standard errors also reveals that the changes in the statistical significance of these effects is not due to relative differences in the changes of the standard errors, for both standard errors increase about 2½ times. From the bottom half of Table 1, we see that the instrumental variable estimation has increased the size of the effect of the Gini index on Jackman, while altering the sign of the effect of Jackman on the 3rd quintile in a direction contrary to the hypothesis.

The estimation in Table 1, then, presents a consistent set of results. In each case, the effect of the measures of inequality on Jackman has increased and remained statistically significant, while the effects of Jackman on inequality have changed in sign contrary to the hypothesis and are no longer statistically significant.

Table 2 shows a similar pattern of results. Inspecting the upper half of this table, we see in column 2 that the effect of Cutright on the Gini index is -.006, with a nonsignificant t-statistic of 1.34. The size of this effect is only slightly reduced from the OLS estimate of -.007, with a significant t-statistic of 1.91. In column 4, however, we see that the effect of the Gini index on Cutright is -40.74, with a significant t-statistic of 2.14. The increase in the size of this effect is 250% over the OLS estimate of -11.64. Again, inspection of the standard errors reveals that the changes in the significance levels are not due to relative differences in changes in the standard errors, since the standard error for the Gini index increases even more than the standard error for Cutright. From this portion of Table 2, we see that the size of the effect of the Gini index on Cutright increases significantly and is also statistically significant, while the size of the effect of Cutright on the Gini index

decreases slightly and is not statistically significant.

The bottom half of Table 2 shows the same pattern. In column 2, we see that the effect of Cutright on the Gini index is .125, with a nonsignificant t-statistic of .739. This represents a reduction of about 30% in the size of this coefficient from the OLS estimate (.180, with a nonsignificant t-statistic of 1.63). In column 4, however, we see that the effect of the 3rd quintile on Cutright is 1.20, with a significant t-statistic of 2.27. This effect represents an increase of 165% in terms of the size of this coefficient relative to the OLS estimate of .452, with a significant t-statistic of 2.06. Again, the difference in significance levels cannot be attributed to relative changes in the standard errors of Cutright and the 3rd quintile, since the standard error of the 3rd quintile increases more than the standard error of Cutright. From this half of Table 2, we see that the instrumental variable estimation substantially increases the size of the effect of inequality on Cutright and somewhat decreases the size of the effect of Cutright on inequality.

In Tables 1 and 2, we find that in the instrumental variables model the effects of democratization on inequality decrease in size or are in the wrong direction and, in no case, are they statistically significant. The effects of inequality on democratization, however, always increase in size, are in the right direction and are, in each case, statistically significant. This same pattern of results has occurred for two different indicators of democratization and for two different indicators of inequality. These results lend more empirical support to the assertion that inequality has an effect on democratization, while giving less support to the assertion that democratization has an important effect on inequality.

In summary, we find that both hypothesized factors help to explain inter-country differences in the degree of democratization: (1) a class structure characterized by greater economic power of middle-income groups and (2) a governmental structure characterized by a more equal distribution of power across governmental branches. We also find that the strength of the state is an important determinant of inter-

country variations in class structure, or inequality; and while there is some effect of democratization on class structure, this effect is considerably reduced when these other variables are included in the model.

Conclusion

We feel it is important to emphasize the tentative nature of these findings. We realize that the sample size is not large (and small sample size can affect the consistency of IV estimates), nor is the sample random (although we have used the only data available). However, the aim of this paper has been replication and reanalysis. Whatever biases there may be in this analysis due to the sample or specification also are present in the empirical research that motivated this analysis. We believe that it is important to replicate first and then to proceed further. For it has become commonplace in the empirical cross-national literature to consider only that democratization affects inequality, and this assertion has been included within a great many models of political development. It would not be correct to conclude that there is no effect of democratization on inequality, since some of these effects (those in Table 2) were not reduced by major proportions in the instrumental variables analysis. Our aim here has been to raise the issue of the alternative specification and to present an analysis of the interrelationships between democratization and inequality.

The primary question with which this paper has been concerned is the relationship between democratization and inequality. In contrast to much of the empirical research which motivated our reanalysis, we make two points in conclusion. First, inequality within countries should be seen basically as a consequence of the class structure of countries. Second, it is this very process of class formation and class dynamics which should be seen as the basic determinant of democratization. In broader theoretical terms, we are raising the issue of the relationship between class structure and competition (and their interactions with the state) to the formation of political regimes.

SOCIAL STATUS, STATUS INCONSISTENCY AND PSYCHOLOGICAL STRESS*

CARLTON A. HORNUNG
University of Maryland

American Sociological Review 1977, Vol. 42 (August):623-638

A method for measuring status inconsistency is presented that permits a comprehensive test of inconsistency theory without the complicated statistical problems that have plagued previous research. An incremental modeling strategy is employed to test for the effects of social status, the effects of status inconsistency, and the effects of statistical interaction between vertical status and inconsistency. The analysis demonstrates the presence of status inconsistency effects. More importantly, however, the results confirm that the effects of status inconsistency are conditional upon location in the stratification hierarchy.

A substantial quantity of research has accumulated involving what Taylor (1973) has termed "theories of social consistency." Under this label, Taylor included certain formulations of social mobility (cf. Sorokin, 1927), status crystallization (Lenski, 1954) and status consistency (Jackson, 1962), the theory of status integration (Gibbs and Martin, 1964; Berry, 1966), and the idea of structural or com-

positional effects offered by Blau (1960) and Davis (Davis et al., 1961). To this list may be added various social exchange formulations such as distributive justice (Homans, 1961), social equity (Adams, 1965) and the theory of status value offered by Berger and his associates (Berger et al., 1972).

Several writers have pointed out formal as well as substantive similarities between the various social consistency theories. Along theoretical lines, Sampson (1963), Geschwender (1967), Mills (1975) and Taylor (1971) have noted that the theories of social consistency parallel the cognitive consistency theories of social psychology (e.g., Osgood's attitude congruity principle, Heider's structural balance principle, and Festinger's dissonance principle) in that both classes of theories predict that an inconsistency or incongruity between

*I would like to thank several people for their comments on earlier versions of this paper. These include Howard F. Taylor, James A. Davis, Donald R. Ploch, David R. Segal, Morris Rosenberg, Duane F. Alwin, Edgar Mills, Jr. and the anonymous reviewers of this journal. Of course, they are not responsible for my misunderstanding their insights. Funds for the analysis of these data were made available by the Computer Science Center, University of Maryland. Danielle Morel deserves special thanks for her attention to detail in preparing the tables and figures.

attributes (e.g., statuses or attitudes) constitutes a source of psychological stress for the individual involved and that this stress in turn leads to some form of adaptive or stress-reducing response. On the methodological side, Blalock (1967) has shown that theories of social mobility, status consistency, status integration and structural effects can be expressed in the same multiple regression format:

$$Y = \beta_1 X_1 + \beta_2 X_2 + \beta_3 (X_1, X_2) + e_y$$

wherein, X_1 and X_2 are statuses occupied by an individual at the same point in time in the case of status consistency and status integration; or the same status occupied at two different points in time in the case of social mobility; or an attitude measured at the individual and aggregate levels, respectively, in the case of structural effects. The third term in the equation denotes some difference (i.e., inconsistency, malintegration, etc.) between X_1 and X_2 that is presumed to affect the dependent variable net of the effects of the statuses or attitudes themselves. Taylor (1973), while demonstrating the utility of the general linear model for assessing and locating inadequacies in theories of consistency, has shown that Blalock's regression strategy is but a limited application requiring interval variables.

Theories of cognitive consistency have received considerable empirical support and occupy a prominent position in social psychology, whereas social consistency theories have not fared as well when subjected to empirical test. The confusing and sometimes contradictory results may be due to simplistic conceptualization and measurement of inconsistency coupled with analysis strategies that are insufficient for the complicated task of disentangling inconsistency effects from the effects of the statuses themselves.

This paper examines the relationship between status inconsistency and psychological stress and involves an examination of assumptions about the effects of inconsistency that have been unchallenged in previous research. This is accomplished by comparing the results obtained with a series of regression models. The most parsimonious of these models involves the linear main effects of education, occupa-

tion and income. More complex models are developed that incorporate terms for type of status inconsistency and then terms for statistical interaction effects between type of inconsistency and vertical status.

Theories of Social Consistency

Theories of social consistency maintain that statuses that are defined as inconsistent (malintegrated or inequitable) are psychologically stressful and that this "socially induced stress" (Martin, 1965:65) leads to an adaptive or stress-reducing behavioral or attitudinal response. Many of the ideas that find expression in the various formulations of social consistency are contained in Hughes' (1945:353-6) classic article "Dilemmas and Contradictions of Status" in which he noted that:

In the struggle for achievement, individual traits of the person stand out as separate entities. And they occur in peculiar combinations which make for confusion, contradictions, and dilemmas of status There tends to grow up about a status, in addition to its specifically determining traits, a complex of auxiliary characteristics which come to be expected of its incumbents If we think especially of occupational status, it is in the colleague-group or fellow-workers group that the expectations concerning appropriate auxiliary characteristics are worked most intricately into sentiment and conduct

According to Hughes, a "specific status" characteristic is the foundation from which expectations arise about the nature of an individual's "auxiliary status" characteristics. The auxiliary characteristics that come to be expected of occupants of a specific status are those auxiliary statuses that occur in frequent combination among individuals possessing the specific characteristic. Conversely, combinations of auxiliary status characteristics that are "peculiar" among incumbents of a specific status are defined as inconsistent and constitute a source of psychological stress for the individuals involved. Thus, for example, the female aerodynamic engineer and the black physician that Hughes talked about occu-

pied inconsistent statuses, because traditionally aerodynamic engineers were male and physicians were white. These inconsistencies were a source of stress for them and for others with whom they interacted.

The definition and measurement of inconsistency that underlies most previous research has not distinguished between specific and auxiliary status characteristics but has assumed, instead, that positions in different status dimensions each give rise to symmetric expectations about other status characteristics of the individual. However, as suggested by Hughes, expectations about relationships between specific and auxiliary status characteristics are asymmetric and involve anticipatory and normative components. Expected status relationships are anticipatory in that if Person believes Other occupies position i in the specific status dimension S (call it $S^{(i)}$), then Person anticipates Other to occupy positions j and k in auxiliary status dimensions A_1 and A_2 (call them $A_1^{(j)}$ and $A_2^{(k)}$).¹ Expectations are normative in that both Person and Other come to believe that $A_1^{(j)}$ and $A_2^{(k)}$ *should* be occupied by individuals possessing $S^{(i)}$. Furthermore, the expected relationships between specific and auxiliary status characteristics are asymmetric in that $A_1^{(j)}$ and $A_2^{(k)}$ are expected of individuals occupying $S^{(i)}$, but a particular category or level of a specific status dimension is not necessarily expected of individuals on the basis of their positions in A_1 and/or A_2 . (For a more detailed discussion of asymmetric status expectations, see Berger et al., 1972:129-31.) Thus, while aerodynamic engineers are expected to be male and physicians are expected to be white, males and whites are not necessarily expected to be engineers or physicians.

Following Hughes, occupational status, which is a salient element of the self-concept (Mulford and Salisbury, 1964) and the single best indicator of social position (Blau and Duncan, 1967), is a specific status characteristic for which combinations of auxiliary statuses such as educa-

tion and income come to be defined as consistent or inconsistent (i.e., "natural" or "peculiar"). On the basis of occupation, individuals are expected (in many instances, legally required) to have attained a certain level of education and to maintain a certain style of life. In this respect, individuals in the same or a similar occupation constitute an equity group (Kemper, 1968) or referential structure which determines the investments the individual legitimately can be expected to make and the rewards he or she legitimately can expect to receive. Levels of investments such as educational attainment or rewards such as income that are higher or lower than expected for a specific occupational status violate this distribution rule and result in psychological stress such as dissatisfaction with current status positions (Hyman, 1967; Hornung, 1972).

Data

The data for this analysis were collected as part of the Princeton Fertility Study (Westoff et al., 1961). Of the 1,265 couples in the first panel of the study, 941 husbands completed questionnaires that included a number of measures of satisfaction with current job and financial situation.

Measures of Psychological Stress

Occupation stress (OS) is conceptualized as a perception of a lack of intrinsic rewards in the occupational role. No pretense is made concerning the exact nature or relative importance of the various components of occupation dissatisfaction which include wages, amount and type of supervision, degree of autonomy and self-expression, physical conditions, hours, etc. (Kalleberg, 1977). Further, no reference to the internalization of the work ethos is intended. Rather, the reference for occupation stress is essentially noneconomic in quality and pertains to the individual's preference for engaging in activities other than his present occupational role.

Financial stress (FS) is conceptualized as the degree to which the individual per-

¹ In the case of nominal status attributes "i," "j," and "k" denote categories, while in the case of hierarchical status dimensions "i," "j" and "k" denote ranks.

ceives his present income as being insufficient to afford the style of life he feels he deserves.

Measures of these stress variables were obtained from a factor analysis of thirteen dichotomous items contained in the husband's questionnaire. Factor scales for occupation stress and financial stress were computed and adjusted to have means of 2.50 and standard deviations of 1.25.

Development of Regression Models

Additive main effects model (Model 1.1). The first regression model involves the additive linear main effects of education, occupation and income status and is written as:

$$Y = \beta_1 E + \beta_2 O + \beta_3 I + e_y \quad (1.1)$$

where E, O and I denote education, measured as the number of years of formal schooling completed, occupation, and income measured as the total salaries and wages received by the individual in the year preceding the date of the interview.² The ability of the linear main effects of status to account for levels of occupation and financial stress experienced by individuals is one criterion for judging the merits of more complex models involving measures of status inconsistency.

The working hypotheses that occupation stress and financial stress are inversely related to education, occupation and income status will be refined as regression models involving status inconsistency variables are developed.

Type of status inconsistency (Models 2.1 and 2.2). Types of status inconsistency are defined in terms of combinations of

education and income that are expected for different occupations. The procedure for measuring inconsistency employed in this analysis was introduced by Goffman (1957) and has at least three important advantages over measurement strategies that have dominated status inconsistency research. First, the procedure used here does not rest on an assumption of a strong or even a moderately strong linear correlation between status hierarchies. The linearity assumption which underlies commonly used measures of inconsistency (cf. Lenski, 1954; House and Harkins, 1975) introduces error into the measurement of inconsistency to the extent that departures from linear relationships between status dimensions are structured in the status expectations held by individuals. Second, the procedure used here takes into account the asymmetric nature of the status expectation process whereas previous measures have assumed the process to be symmetric. Third, nominal status characteristics such as sex or marital status can be used, whereas previous measures have been restricted to status dimensions that can be rank-ordered.

Although the procedure is used here with occupation as the specific status and education and income as auxiliary statuses, alternative analyses may be undertaken in which, for example, race, ethnicity, sex or education is defined as the specific status and occupational prestige, income or other status characteristics of individuals are conceptualized as auxiliary statuses. Further, the measurement procedure is easily generalized for use with four or more status characteristics (see Ploch, 1968, for an alternative methodology).

To determine types of status inconsistency, education and income are cross-tabulated within each of the census categories of occupation. Levels of education and income between the 30th and 70th percentiles of their respective distribution within categories of occupation are defined as "consistent" for that occupation, while levels of education and income below the 30th percentile are "inconsistent-low" and values above the 70th percentile are "inconsistent-high."

² It should be noted that the measure of income status pertains to a different point in time (i.e., the year preceding the date of interview) than the measures of education and occupation status (i.e., status at time of interview). This temporal difference is unlikely to introduce "differential" measurement error into the main effects of the status variables, given that the differences apply across all cases. However, distortions of indeterminant magnitude may be introduced in the inconsistency effects, given that mobility between the two points in time to which the status measures apply will mean that individuals are scored "consistent" while at time of interview they are "inconsistent" and vice versa.

		Income		
		Low	Consistent	High
Education	High	Education-High Income-Low Type 1	Education-High Income-Consistent Type 2	Education-High Income-High or Occupation-Low Type 3
	Consistent	Education-Consistent Income-Low Type 4	STATUS CONSISTENT Type 5	Education-Consistent Income-High Type 6
	Low	Education-Low Income-Low or Occupation-High Type 7	Education-Low Income-Consistent Type 8	Education-Low Income-High Type 9
		30th Percentile		70th Percentile
		30th Percentile		70th Percentile

Figure 1. Type of Inconsistency

This yields nine combinations for each occupation.³ Eight of these combinations are mutually exclusive types of status inconsistency (see Figure 1). The intersection of consistent education and consistent in-

come defines the status consistent type (type 5).

Model (2.1) isolates the effects of type of inconsistency controlling for education, occupation and income status:

$$Y = aU + b_1E + b_2O + b_3I + \sum_{i=1}^{k-1} c_i T^{(i)} + e_y \quad (2.1)$$

where $T^{(i)}$ are binary coded terms denoting the eight types of inconsistency. A model for determining the effects of type of inconsistency ignoring the main effects of the status variables is:

$$Y = aU + \sum_{i=1}^{k-1} c_i T^{(i)} + e_y \quad (2.2)$$

In both of these models, the vector for the status-consistent type is deleted to eliminate exact linear dependence. Consequently, the coefficients c_i measure the increase or decrease in Y associated with

³ An examination of the education and income distributions among professionals revealed that nearly 25 percent were in the two highest income categories and over 43 percent were in the highest category of education. In view of the skewness of these distributions, inconsistent high categories of income and education were not defined for professionals. There is some theoretical basis for this. It is questionable whether individuals in the highest occupation could be considered by others to have attained too much education or too high an income. In contrast, education and income low values were defined for the lowest occupation meaning that even laborers are expected to have attained some formal education and earn a minimal income.

The nine categories of type of inconsistency formed in this manner are exhaustive and mutually exclusive. This avoids important logical and statistical problems which have been encountered in previous inconsistency research using two factor comparisons for types of inconsistency (cf. Berry and Martin, 1972).

the i^{th} type of status inconsistency relative to the mean level of stress among status consistents (for alternatives to a +1,0 coding scheme, see Melichar, 1965; Cohen, 1968; Lyons, 1971; MacDonald, 1973; Kerlinger and Pedhazur, 1973; Wolf and Cartwright, 1974).

Equity theory provides a convenient rationale for predicting certain types of status inconsistency to be more psychologically stressful than others. Stress is predicted to be greatest in conditions of *inequity-disadvantage*, which exists when the rewards received by an individual are less than he or she could legitimately expect. Lower stress is expected in conditions of *inequity-advantage*, when rewards received are greater than can be legitimately expected. The lowest stress (i.e., an absence of stress) is expected in a condition where the rewards received are equitable for the investments and costs incurred (Cook, 1975).

Considering years of education as an investment and occupation as a reward, types 1, 2 and 3 of inconsistency are conditions of inequity-disadvantage; types 7, 8 and 9 are conditions of inequity-advantage; and types 4, 5 and 6 are conditions of equity. Considering the occupational role as a cost and income as a reward, inconsistency types 1, 4 and 7 are conditions of inequity-disadvantage; types 3, 6 and 9 are conditions of inequity-advantage; and types 2, 5 and 8 are conditions of equity. Further, the equity or inequity between educational investments and income rewards can be derived from the equity relationships between education and occupation and between occupation and income. In this way, inconsistency types 3, 5 and 7 are derived to be conditions of education-income equity; types 1, 2 and 4 are derived conditions of inequity-disadvantage; and types 6, 8 and 9 are derived conditions of inequity-advantage.

The combinations of these equity-inequity conditions generate predictions about the rank-order effects of types of inconsistency. Specifically, in the regression of occupation stress on types of inconsistency, the following relationship between coefficients is predicted:

$$c_1 > c_2 = c_4 > c_3 = c_7 > c_6 = c_8 > c_9 > 0.$$

The regression of financial stress on types of inconsistency is predicted to show the following:

$$c_1 > c_4 > c_2 = c_7 > c_3 = c_8 > c_6 > c_9 > 0.$$

Note that all types of status inconsistency are predicted to be more stressful than consistency (i.e., all c_i coefficients are predicted to be positive); that type 1 inconsistency is predicted to lead to the highest occupation and financial stress; that education-low, income-high (type 9) is predicted to be the least stressful type of inconsistency; and finally, that inconsistency types 2 through 8 are predicted to have different consequences for occupation and financial stress.

Vertical status and type of inconsistency (Models 3.1, 3.2 and 3.3). The third set of models in this analysis explores the possibility of statistical interaction between type of inconsistency and location in the vertical stratification hierarchy. Models (2.1) and (2.2) assume, as has previous inconsistency research, that the effects of inconsistency are uniform at all points in the vertical hierarchy. In other words, the effects of education-low, income-high have been assumed to be the same for clerical workers as for skilled trades workers. Although there is some evidence that the effect of inconsistency is conditional upon vertical status (cf. Goffman, 1957; Bauman 1968; Hornung and McCullough, 1977), there has been no systematic attempt to locate specific interaction effects. If interaction effects are documented, then the assumption of uniform effects of inconsistency breaks down and a potential source of the confusing and sometimes contradictory results of previous inconsistency research (cf. Jackson and Curtis, 1972) has been identified.

Model (3.1) yields the total effects of vertical status (measured as occupation) and type of inconsistency:

$$Y = aU + \sum_{i=1}^{k-1} \sum_{j=1}^{m-1} b_{ij} 0^{(i)} T^{(j)} + e_y \quad (3.1)$$

where $0^{(i)}$ and $T^{(j)}$ are binary-coded occupation and type of inconsistency variables, respectively. It can be shown (Taylor, 1973:1210) that this equation is

identical to a subclass equation written as:

$$Y = \sum_{i=1}^k b_i C^{(i)} + e_y$$

where $C^{(i)}$ are unique combinations of occupation and type of inconsistency.

Model (3.1) and the subclass equation are "total effects" equations in the sense that they yield the maximum explained variation in Y that can be achieved with vertical status and type of inconsistency. However, neither of these equations partition explained variation into that due to the additive effects of occupation and type of inconsistency and that due to their statistical interaction. To accomplish this partitioning and to isolate the proportion of variation in stress explained by the conditional relationship between type of inconsistency and vertical status, Model (3.1) is compared to an equation that assumes the effects of vertical status and inconsistency to be additive. Model (2.1) is not suitable as an additive effects baseline because it includes terms for the effects of education and income in addition to those of occupation and type of inconsistency. An equation suitable for our purposes is written as:

$$Y = aU + b_1 O + \sum_{j=1}^{m-1} c_j T^{(j)} + e_y \quad (3.2)$$

where the effects of vertical status are assumed to be linear. Because of the restrictiveness of this assumption, Model (3.2) may produce inflated estimates of interaction effects when compared to Model (3.1). A more conservative estimate of the interaction sums of squares is obtained by comparing Model (3.1) with an equation that relaxes the linearity assumption, thereby enabling vertical status to explain a larger proportion of the variation in Y . Such a model is written as:

$$Y = aU + \sum_{i=1}^{k-1} b_i O^{(i)} + \sum_{j=1}^{m-1} c_j T^{(j)} + e_y \quad (3.3)$$

If Model (3.1) explains significantly more variation in stress than the conservative Model (3.3), then there is strong evidence of interaction effects between type of status inconsistency and location in the stratification hierarchy.

Type of Inconsistency and Stress

The results are summarized in several tables beginning with Table 1 which presents the unstandardized regression coefficients and proportion variation explained for the first two sets of models. Model (1.1) assumes additivity and linearity and shows that years of education, occupation, and total salary and wages are, as predicted, inversely related to both occupation and financial stress. While each of the main effects is significantly related to occupation stress with the single best predictor being years of education, only occupation and income are significantly related to financial stress. The linearity and additivity assumptions restrict the main effects to explaining a modest 12.9 and 11.2 percent of the variation in occupation stress and financial stress, respectively. These results are one criterion for assessing the utility of less parsimonious models which incorporate terms for status inconsistency.

There is some debate over what constitutes an appropriate test of consistency theory (cf. Hope, 1975). There are those who maintain that theories of consistency have scientific value if measures of inconsistency are capable of explaining variation in the dependent variable left unexplained by the additive effects of the statuses (cf. Olsen and Tully, 1972). The appropriate test of status consistency according to this position is a comparison of the proportions of variation explained by Model (2.1) and Model (1.1). However, it also can be argued that theories of consistency are scientifically useful if they yield accurate predictions of the effects of inconsistency without reference to the main effects of the statuses. In this case, the appropriate test of status consistency is a comparison of the predicted and observed coefficients for the effects of type of inconsistency obtained with Model (2.2).

Model (2.1) finds type of status inconsistency adding only 2.1 percent to the explanation of occupation stress and even less to the explanation of financial stress. The poor explanatory power of type of inconsistency also occurs in Model (2.2) which ignores the main effects and explains less than 2 percent in occupation

Table 1. Unstandardized Regression Coefficients Models 1.1, 2.1 and 2.2

stress but 5.7 percent in financial stress. Accordingly, in terms of the first criterion for assessing the theory, compared to the explanatory power of the main effects, type of status inconsistency does not appear to have much scientific value. However, Model (2.2) does yield results that provide support for the theory, at least in terms of the second criterion.

Table 2 shows that the mean stress levels for each type of inconsistency conform quite closely to their predicted rank-order. Seven of the eight types of inconsistent individuals report significantly higher occupation stress and five report significantly higher financial stress than status-consistents. Occupation stress is high for types 9, 2 and 4, moderate for types 1, 8 and 6, low for types 7 and 3, and lowest among status-consistents (type 5). Financial stress is high for types 4, 1 and 7, moderate for types 2 and 8, and about equally low for types 6, 5, 3 and 9. A finding that does not conform to the predictions is that education-low, income-high inconsistency (type 9), which was predicted to be the least stressful of the inconsistency types, has the lowest level of financial stress but the highest occupation stress.

Types of inconsistency that involve inequity-disadvantage between education and income (types 1, 2 and 4) have high means on both occupation stress and financial stress. The high financial stress reported by these types of inconsistent is a function of the low financial returns for the level of investments made. Kalleberg's (1977:138) analysis of job satisfaction would suggest that the observed high occupation stress results from highly educated workers being overtrained for their jobs and therefore not deriving intrinsic satisfactions from their occupational role. Our results generally support Kalleberg's argument but suggest further that the relationship between educational investments and occupation stress is conditional upon the level of financial rewards received. Specifically, *over*-education leads to occupation stress only when the financial returns are less than equitable for the investments made. Type 3 inconsistent report low financial stress and low occupation stress suggesting that financial re-

Table 2. Stress by Type of Status Inconsistency

turns that are above what the individual can legitimately expect on the basis of his or her occupation reduce the stress produced by overtraining if the income received is equitable for the higher than expected education. In this respect, equity between education and income apparently mollifies the stresses of inequity-disadvantage between education and occupation and inequity-advantage between occupation and income. In contrast, *under*-education combined with higher than expected income (i.e., inequity-advantage as in type 9) leads to high occupation stress. This probably results from undertrained individuals working harder at their jobs and thereby deriving less satisfaction from the occupational role per se and from being resented by their co-workers for having an income above a level defined as just (Homans, 1961).

This analysis confirms the presence of status inconsistency effects and demonstrates that types of inconsistency cannot be assumed to have the same consequences for all measures of stress or, for that matter, all attitudes and behaviors. However, the theoretical importance of these findings cannot be assessed without considering the results obtained with the third set of regression models which isolate the effects of types of inconsistency at different points in the stratification hierarchy.

Model (3.1) accounts for 24.7 and 17.3 percent of the variation in occupation and financial stress, respectively. More impor-

tant, assuming linear effects of vertical status finds 14.4 and 8.2 percent of the variation accounted for by the interaction of type of inconsistency and vertical status. When the assumption of linear vertical status effects is relaxed, 6.2 percent of the variation in the occupation stress measure and 5.4 percent in financial stress remain attributable to statistical interaction between vertical status and inconsistency. These results are strong evidence that the effects of types of status inconsistency are conditional upon the individual's position in the occupation hierarchy.

Table 4 presents the mean occupation and financial stress by type of status inconsistency and vertical status. It must be mentioned that the frequencies in many of the cells are small and therefore the results must be interpreted with caution because of the sensitivity of the mean to sampling error.

Table 4 reveals that the effects of status consistency as well as inconsistency are conditional upon vertical status. No combination of education and income status is found to have the same consequences at all points in the stratification hierarchy. Instead, the level of both occupation and financial stress is a function of vertical status and type of status inconsistency.

The means in each column of Table 4 are graphed in Figure 2 with the X axis divided into four segments corresponding to the semi-permeable boundaries between lower blue-collar, upper blue-collar, lower white-collar and upper

white-collar *classes*. Each class is, in turn, divided into a lower and upper *stratum*.

If the consequences of type of inconsistency were independent of vertical status, then the mean stress levels could be connected by straight lines parallel to the X axis (i.e., $b_1 = b_j = \dots = b_m = 0$, where i is type of status inconsistency) and the effects of types of inconsistency would be indicated by different Y intercepts ($a_1 \neq a_j \neq \dots \neq a_m$). If there were effects of vertical status but no effects of inconsistency, the slopes would be equal and non-zero and the Y intercepts would be equal. Additive effects of vertical status and type of inconsistency would produce equal non-zero slopes and different Y intercepts, while unequal slopes and different intercepts would indicate additive and interaction effects between vertical status and inconsistency. The interaction effects of inconsistency and stratum are indicated

by line segments with non-zero slopes, while interaction between inconsistency and class are indicated by line segments of differing (average) heights above the X axis or significantly different slopes.

The lines plotting occupation stress and those for financial stress covary in a manner that would indicate that the psychological consequences of status consistency and inconsistency are conditional upon vertical status and that the results are not simply an artifact of small Ns. This is substantiated by the pattern of findings for status-consistents in which there are a sufficient number of cases in each occupation to be reasonably confident in the stability of the means of the stress measures.

The pattern of results suggests that if we think in general terms about education as an investment of human capital that is a requisite for an occupational role and of income as an expected perquisite, then the

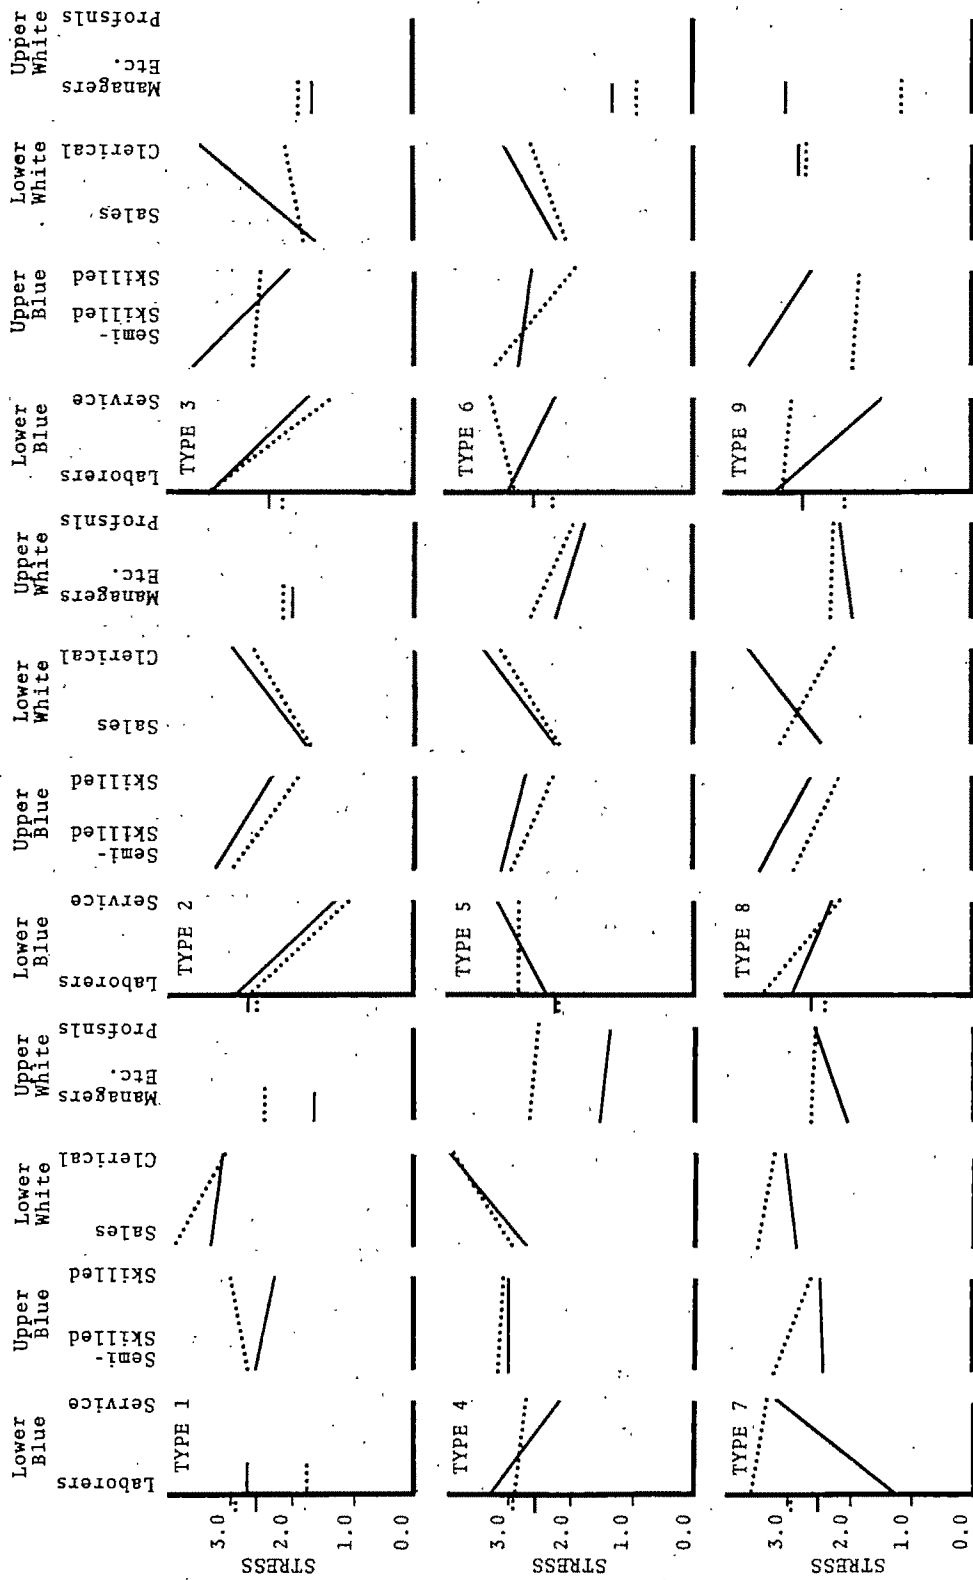

Figure 2. Stress by Type of Inconsistency by Vertical Status Financial Stress

psychological consequences of inconsistency (i.e., inequity) are conditioned by position in a vertical hierarchy of occupations. The observation that status consistency is not always associated with low stress is particularly significant since the cornerstone of previous research has been the assumption that status consistency was not stressful regardless of vertical status. On the contrary, status-consistents with jobs in the top stratum of the lower blue-collar (i.e., service workers) and lower white-collar (i.e., clerical) classes as well as status-consistents with jobs located in the bottom stratum of the upper blue-collar (i.e., semi-skilled) and upper white-collar (i.e., managers, etc.) classes report *both* high occupation stress and high financial stress. It is noteworthy that status-consistents in these strata experience greater stress than many status-inconsistent. One explanation for this is that status consistency is stressful when consistency across status dimensions means that future mobility is unlikely. For example, clerical workers who have attained the expected level of education and earn the expected income for their occupation are likely to lack the financial resources and security to enter the ranks of the self-employed or the educational attainment to become professionals. In this respect, status-consistents in these strata may come to regard their occupations as mobility traps offering little opportunity to improve their financial situations or to move into other lines of work.

The graphs for the eight types of status inconsistency provide some indication of the psychological consequences of status inconsistency at different points in the hierarchy of occupations. Both occupation stress and financial stress are functions of class position and relative amount of income received among individuals with more than the expected level of education for their occupation. When income rewards are relatively low (type 1), occupation stress decreases within each class; but when income rewards are consistent (type 2) or higher than expected (type 3), occupation stress decreases within the blue-collar classes but increases within the lower white-collar class. Among these overtrained individuals, financial stress

increases within the upper blue-collar class and decreases within the lower white-collar class when the level of income rewards received is less than expected. However, this pattern reverses when income is consistent or higher than expected so that financial stress decreases within the blue-collar classes and increases within the white-collar class. In contrast, the results for types 7, 8 and 9 which involve inconsistent-low education show that financial stress decreases within each class, independent of whether the income rewards received are lower than expected (type 7), consistent (type 8) or higher than expected (type 9) for the occupation. In other words, the level of financial stress experienced by undertrained individuals is a function of whether they are in a high or low stratum job within an occupational class. However, occupation stress experienced by undertrained individuals is a function of both position within a class and the relative amount of income rewards received. Individuals in upper stratum jobs with less than the expected level of education experience high stress unless they receive the expected or higher than expected income rewards. Jobs in the upper stratum of a class place more emphasis on training and education than lower stratum jobs in the same class and, as a result, undertrained individuals experience high stress in upper stratum jobs when their income rewards do not testify to their ability to satisfactorily perform the occupational role (i.e., when income rewards are not consistent or higher than expected).

Conclusions

The discontinuity of the lines in Figure 2 suggests that there are divisions in the hierarchy of occupations that affect the psychological and, perhaps, other consequences of status consistency and inconsistency. This implies that these divisions are meaningful for the way individuals perceive and evaluate the equity of their educational investments and income rewards. Distribution rules that define the level of investments and rewards that individuals can legitimately be expected to make and receive appear to be based on

position within an occupational class. Moreover, position within a class affects the kinds of stress experienced by individuals in different conditions of inequity. Individuals in low stratum jobs within classes generally react similarly to each type of status inconsistency while individuals in high stratum jobs also react similarly, but the level of occupation stress and financial stress they experience differs from that experienced by those in lower stratum jobs.

The theory and measurement of status consistency presented here was found to predict accurately higher levels of stress among status-inconsistent than among individuals occupying status combinations that were defined as consistent. This finding by itself, however, is not sufficient to claim that social consistency theories in general, or status consistency theories in particular, are as sound as cognitive consistency theories. However, the finding that type of status inconsistency interacts with vertical status indicates that the assumption of additive effects of status and status inconsistency is misleading and is a potential source of the confusing findings reported in previous research. In the future, adequate tests of social consistency theories will require the use of analysis strategies that partition explained variation into that accounted for by the main effects, the effects of inconsistency and higher-order statistical interactions between the main effect variables and measures of inconsistency.

DISTRIBUTIVE JUSTICE AND EARNED INCOME*

GUILLERMINA JASSO

Barnard College, Columbia University

PETER H. ROSSI

University of Massachusetts, Amherst

American Sociological Review 1977, Vol. 42 (August):639-651

This is an empirical exploration of the normative criteria for just distributions of earned income. The results indicate that the fairness of earnings is judged relative to a set of criteria which includes (but perhaps is not limited to) formal educational attainment, occupational attainment, sex, marital status and knowledge of family earnings. That is, both merit and need factors combine to produce judgments of fairness and unfairness. These criteria for just earnings appear to be held consensually and are largely independent of the raters' observable demographic attributes.

Introduction

Empirical research on distributive justice has focused largely on the consequences for subjects of observing and/or participating in situations defined by an experimenter as "unjust." This large and impressive body of literature (whose most recent review appears in Adams and Freedman, 1976) has focused primarily on the proper specification of the determinants of "inequity effects" (thought to be anger in the under-reward case, guilt in the over-reward case) and certain not-yet-well-understood redressing behaviors. The favorite research design involves observing the reactions of subjects whose expectations, furnished by the investigator, are violated. For example: Walster and Austin (1974) measured the contentment and distress of subjects who, led to expect "normal \$2 pay" for performing a proofreading task, were paid varying amounts; McCranie and Kimberly (1973) constructed a referential standard whose "three ranks were always described as consistent (i.e., all high) so that the Ss

would have a highly stable referent with which to compare ego"; and Cook (1975:382) supplied subjects with the implicit distribution rule that "pay should be allocated on the basis of ability."

The research designs described above as archetypical bypass the critical questions of the justice problem: (1) Is there a general standard (or standards) that guides judgments concerning distributive justice issues in such crucial areas as earnings? (2) How much consensus is there concerning such standards of justice? Such research designs also ignore the basic question about the etiology of the standards of justice, the major puzzle being whether they are derived from actual distributions of resources—an existential referent—as Homans (1974; 1976) has suggested, or whether they are plucked from some primordial image of "what ought to be"—a utopian referent—as Berger et al. (1972) have suggested.

Laboratory experiments undoubtedly have pursued the right tactic in attempting to fix experimentally the normative framework into which subjects are to be placed. The existence of consensually held standards of justice is so critical to the experiments that it would be damaging to assume that they are brought to the experimental setting by subjects. Yet from the viewpoint of attempting to assess the importance to real-world behavior of distributive justice processes, the existence and prevalence of such frameworks must be taken as problematic.

Nor is this question merely one of con-

* The research reported in the article was conducted as part of a program of research supported by MH 242254, "Experimental Studies of Household Social Status." cern to the social scientist interested in real-world applications of the concepts and theories of distributive justice. The two major theoretical formulations decidedly regard as problematic the content of the justice rules. The Berger et al. (1972) model defines a situation as unjust if a real-world actor's level of a goal-object differs from the level of the goal-object received by his/her counterpart in a "referential structure." Note that this formulation is amenable to both the utopian and the existential conceptions of the sources of justice. The Homans (1974) model defines justice as equality of actors' profits/investments ratios. Both models are essentially multivariate and both recognize the multiplicity of dimensions deemed relevant to the justice evaluation of shares of social resources. Both require a common metric such that the value or "worth" of levels of characteristics or inputs and levels of outcomes can be established unambiguously (cf. Homans, 1976:232).

However, the research tradition has avoided the question of the just association between levels of actors' attributes and levels of outcomes, apparently preferring to relegate it to the givens of the theory. Thus, in a well-formalized recent piece, Cook (1975:374) consigns to the scope conditions of a theory of the emergence of justice concerns in social systems: (1) the existence of a distribution rule that "specifies how the dimensions of evaluation in a social system (e.g., skill level, seniority, etc.) are related to the allocation of valued outcomes" and (2) the perception of the legitimacy of the distribution rule, that is, of "the extent to which the distribution rule is supported normatively in the social system." Cook (1975:373) writes, "It would be interesting, of course, to address questions concerning the legitimacy of the distribution rules (e.g., that workers with more seniority should receive higher salaries)." Current empirical studies in distributive justice thus expend their major efforts in attempts to predict reactions to various forms of inequity, the latter being defined within the context of the research setting.

But one investigator's assumption is another's research question. Convinced

as we are that soup should come before salad—that legitimate distribution rules¹ should be endogenous to an empirical theory of distributive justice—we undertook to animate the Berger et al. (1972) referential-structure "persons," to quicken the terms in the Homans ratios, and to do so quantitatively.

But suppose that selection of referential standards, relevant inputs or distribution rules is idiosyncratic, suppose that the world is as Walster et al. (1976:4–5) observe:

Ultimately, equity is in the eye of the beholder. An individual's perception of how equitable a relationship is will depend on *his* assessment of the value and relevance of the various participant's input and outcomes If participants do calculate inputs and outcomes differently—and it is likely that they will—it is inevitable that participants will differ in their perceptions of whether or not a given relationship is equitable. Moreover, "objective" outside observers are likely to evaluate the equitableness of a relationship quite differently than do participants.

We suggest that if referential standards turn out to be idiosyncratic, then an empirical theory of distributive justice is but a drollery. Deprived of agreement on what is just and unjust, our models would be unable to predict anything social (a point implied by Homans [1976:232] and well understood by Cook, as the scope conditions show).

Prediction is not the sole impetus behind our search for consensual referential standards. These referential standards or distribution rules are part of what Rawls (1971:4–5) had in mind in his normative theory of justice:

A society is well-ordered when it is not only designed to advance the good of its members but when it is also effectively regulated by a public conception of justice. That is, it is a

¹ We consider that a distribution rule may be a set of guidelines, such as a triage policy, or that it may be an empirically-derived function, such as earnings returns to specific characteristics. In any case, these distribution rules describe "what is." Their legitimacy refers to "what ought to be." Manipulation of these two variables may lead to alternative research designs. For example, subjects could be asked to evaluate alternative distribution rules or they could be asked to devise such a rule.

society in which (1) everyone accepts and knows that the others accept the same principles of justice, and (2) the basic social institutions generally satisfy and are known to satisfy these principles.

We consider important a research program aimed at documenting empirically the standards thought just for the distribution of the social primary goods, chief among them the Weberian hierarchies of wealth, power and prestige, but also the sub-hierarchies, such as educational attainment. Empirical work of the past ten years has made notable advances in documenting the *actual* distributions of earnings, educational attainment, occupational attainment and occupational prestige. A parallel assessment of *just* distributions would permit preliminary answers to the theoretical question of the sources of justice and to the practical question of everyday discourse, "What is fair?"

In the empirical inquiry reported here, we restrict attention to the earnings distribution. Earnings are of overwhelming importance because, for most persons, they are the sole source of monetary income, which is critical to so many aspects of life in an industrial state. Moreover, money as a variable possesses that (blessed) intrinsic quantifiability.

There are many possibilities for the just distribution of earnings. One is equality, that is, zero variance, with equal shares for all workers. A second possibility combines dispersion with random criteria for allocation. In this case, the distribution of earnings thought just may have a given variance, but allocation of differently-sized shares would be on a random basis (e.g., by lottery). A third possibility combines dispersion with systematic criteria for allocation of the differently-sized earnings shares. These criteria could be any of a large number of personal or family characteristics, such as age, sex, native ability, effort, need or even seemingly capricious criteria such as number of lines in the right palm.²

² Choice of a just distribution of earnings may be considered as a branching problem. First, a decision is made on the proposition that all shares ought to be equal. If that decision is negative, then there are two additional decisions to be made, one on the amount

This third possibility may be regarded as rational selection of a just distribution out of all the possible unequal distributions. The criteria chosen reflect alternative conceptions of just bases or claims for earnings allocation. For example, earnings may be viewed as payment for the performance of a job, in which case the criteria would be work-related; or earnings may be viewed as support for a family, in which case certain indicators of need would be salient criteria.

There are many reasons to believe *a priori* that our society represents a particular manifestation of the third form of justified inequality. Common wisdom stresses that there should be some sort of fit between a person's qualifications and performance and his/her earnings. All the tell-tale traces of distribution rules suggest achievement through personal qualities as the basic justification for income differentials with some modifications to take into account the varied income needs of persons and households under certain conditions (e.g., young children, disabling illnesses). The details of the underlying structure of justice rules are not as obvious, however. Whether educational attainment, for example, overrides the justification for income that may be generated by responsibilities for dependents is not at all clear.

The general aims of the research reported below are to uncover some of the features of the normative structure underlying distributive justice judgments concerning earnings. We take as problematic, in the first place, the existence of such a structure and, in the second place, the specific provisions within such an existing structure.

Method

Our research strategy is to elicit from a reasonable sample of respondents a set of judgments about the justice of the earnings enjoyed by a variety of fictitious individuals and families. These judgments are

of dispersion to be allowed and the other on whether the criteria for allocation ought to be random or systematic. These possibilities suggest a variety of research designs, thus making possible the reliability testing of procedures.

obtained in household interviews by presenting to the respondents a set of descriptions of individuals and families (called vignettes). The set of vignettes presented to each respondent has certain important features: the distribution of earnings across such vignettes is rectangular, which maximizes the earnings variance. Earnings are random with respect to all other characteristics, thus assuring a test of the relative importance of the various justice rules. Finally, the overall patterning of judgments about such a set of vignettes allows inferences concerning collectively preferred earnings distributions.

The respondent sample. Block quota sampling methods were used to choose a respondent sample of 200 white adults residing in private households in Baltimore City. Sex quotas were fixed to ensure that equal numbers of adult females and males were interviewed. Although block quota sampling methods have known biases (cf. Kish, 1965), their considerably lower costs offset the greater precision afforded by more rigorous area probability sampling methods for studies in which population estimates are not critical.³ As will be shown below, the fact that there are few subgroup differences within our sample on crucial findings leads us to have some confidence in the external validity of this particular sampling strategy.

The vignette sample. Each fictitious person was described in terms of a combination of characteristics, as follows:⁴

Sex

Marital status—Single or married.

Number of children—Zero to six, in increments of one.

Education— Years of formal education, ranging from completion of

seventh grade to college graduation, in increments of one year.

Occupation—Ninety-six occupational titles whose prestige scores, standardized by Bose (1973) for the Baltimore area, ranged from 8.0 to 95.8, plus the designation "Unemployed and looking for a job" and the sex-restricted title "Housewife."

Earnings— Fifteen levels of annual earnings ranging from \$2,000 to \$40,000; thus, a married couple may have combined earnings ranging from \$2,000 to \$80,000.⁵

Half the vignettes described one adult person designated either married or single but providing no information about the spouse, if married. These vignettes mirror some real-world situations, either of single persons living alone or of married persons about whose spouses one has no knowledge. The other half of the vignettes describe married couples, with all information given for both husband and wife. The vignettes were generated by computer and printed on IBM cards, the program randomly selecting characteristics from within each list for each person described in a vignette. Thus, for a one-person-single vignette, sex was randomly selected, then occupation, an educational level and finally an earnings amount were selected. Restrictions to eliminate nonsensical combinations (e.g., a physician with an eighth-grade education) were imposed *a priori*. To eliminate the possibility of zero earnings on a vignette, the Unemployed and Housewife designations were restricted to one such title per married couple.

The vignettes thus generated constitute an almost completely crossed experimental design. Obviously, the characteristics of vignettes do not have the same intercorrelations as one would find among concrete individuals or families. Indeed, this is one of the virtues of the vignette

³ Comparisons with census (U.S. Bureau of the Census, 1970) estimates for whites in Baltimore City show that our sample is similar to the parent population in mean years of school completed (12.3), but somewhat younger (43.8 versus 48.4 years) and more married (67% versus 56%), a result perhaps of our setting sex quotas at parity. The respondents' tract median incomes ranged from \$5,442 to \$16,685.

⁴ We decided to restrict vignette characteristics to a very small set because each additional factor would considerably lessen the efficiency of the vignette samples. However, race, ethnicity, length of employment and other variables excluded from this study will be added to future studies.

⁵ The levels of individual earnings are in increments of \$1,000 between \$2,000 and \$8,000, of \$2,000 between \$8,000 and \$14,000, of \$4,000 between \$14,000 and \$22,000, and of \$6,000 between \$22,000 and \$40,000.

technique. Because correlations are much lower than obtained in the real world, respondents are forced to make discriminations that involve taking into account disparate attainments and characteristics of individuals and families.

Ten samples of sixty vignettes each were drawn, for a total of 600 distinctly different vignettes.⁶ The vignette samples were drawn so that each contained five vignettes describing single males, five describing single females, ten each of vignettes describing married males and married females (with no information provided about a spouse) and thirty vignettes describing married couples. The ten vignette samples were systematically distributed with equal probability across respondents, each sample being given to twenty respondents, for a possible total of 12,000 judgments. To preclude order effects, each vignette set was well-shuffled.

Interviews lasting about half an hour were conducted by experienced professional interviewers.⁷ Each respondent was handed a set of vignettes and a box with nine slots, each labeled with a number and a description corresponding to a level of the justice evaluation variable, ranging from "-4 Extremely Underpaid," through "0 Fairly Paid," to "+4 Extremely Overpaid." The task given to the respondent was to place each vignette in the slot that corresponded to the respondent's justice evaluation of each vignette.⁸ The interviewers reported

⁶ Each of the ten vignette samples may be regarded as a random sample of a population composed of all the permissible combinations of the personal characteristics. Since each person in each one-person vignette could take on one of two sexes, one of two marital statuses, one of 99 occupational titles, one of ten educational levels and have from zero to six children (if married), the population of possible vignettes for the one-person vignettes was very large. Of course, the married-couple vignettes have a much larger population of possible combinations. Because the vignette samples were drawn at random, each sample has the same statistical properties as the parent population and varies from it only within the limits of sampling error. Hence, each sample is a replication of an incompletely crossed factorial design and has most of the desirable statistical properties of such designs.

⁷ Sidney Hollander and Associates, a well-known Baltimore survey firm, collected the interviews in early 1974.

⁸ The actual wording of the item was as follows: "People and their jobs differ in a lot of ways. We

that the respondents generally approached the rating task with seriousness, a view borne out by the number of ratings made, a total of 11,806, or over 98% of the possible ratings.

Special measurement considerations. While most of the variables are measured and coded conventionally,⁹ the fairness rating deserves special comment. The nine-category fairness-rating scale represents an attempt to break into the underlying continuum of perceived relative unfairness with a minimum of bias and a maximum of field utility. The scale works very well in the personal household interview situation. Its major weakness is that the discrete category values reduce the fineness that respondents may want to make in their justice discriminations, forcing them to stay within a set range and to round off their judgments. We assume that rounding errors are unbiased, i.e., have a mean of zero. The scale's major strength is that the combined use of verbal and numerical labels may evoke a sense of intervalness. Our hope that we have attained a better-than-ordinal scale hinges on those labels (and on the large number of ratings).

have made up descriptions of different kinds of people and jobs. Here is a box with nine different slots in it. Here is a card with a description of a person and job.

- a. Please put the card in the slot labeled Fairly Paid if you think that the salary is about right for the person, that is, if you think that the salary on the card is fair payment.
- b. Put the card in the slot labeled Extremely Overpaid if you think that the money is way too much payment for these people, that is, if, taking everything into account, you think that they're very much overpaid.
- c. Put the card in the slot labeled Extremely Underpaid if you think that the money is way too little payment for these people, that is, if, taking everything into account, you think that they're very much underpaid.
- d. If you think that the salary is a bit too much or a bit too little, that is, if you think that it belongs somewhere between the most overpaid and the most underpaid, then just put the card in the slot that you think matches the fairness or unfairness of the salary.

⁹ The quantitative variables were coded with their raw values, except for earnings, which was coded in thousands of dollars. Occupation was coded with the prestige scores standardized for the Baltimore area by Bose (1973). Sex and marital status entered the regressions as dummy variables, with the categories "single" and "male" coded zero.

Table 1. Distributions of Income-Fairness Ratings by Type of Vignette

Fairness Rating	Type of Vignette					
	Single Female	Single Male	Married Female	Married Male	Married Couples	All Vignettes
Extremely Underpaid (-4)	14%	18%	14%	19%	7%	12%
Much Underpaid (-3)	8	12	8	12	9	9
Somewhat Underpaid (-2)	7	10	10	12	10	10
Slightly Underpaid (-1)	11	10	11	11	11	11
Fairly Paid (0)	26	19	26	21	24	23
Slightly Overpaid (+1)	10	8	9	8	10	10
Somewhat Overpaid (+2)	7	8	9	8	10	9
Much Overpaid (+3)	7	7	6	5	10	8
Extremely Overpaid (+4)	10	8	6	5	9	8
100% =	[996]	[998]	[1991]	[1995]	[5826]	[11806]
Average Rating =	-.20	-.61	-.42	-.88	+.10	-.23

Our research design, then, assumes that persons, in fact, make judgments about the fairness or relative unfairness of resource allocation. Happily, this is a short-lived assumption, since data collection soon confirms it. We further assume that the individual's justice conceptual space is a continuum with a mid-point of fairness and two extreme poles of unfairness.¹⁰ Since the zero point represents fairness, we regard the fairness measure as a continuous scale of degrees of unfair payment ranging from underpayment through a midpoint of fair payment to extreme overpayment.

Results

The distribution of ratings received by the approximately 12,000 vignettes rated

by our respondents is shown in Table 1. If respondents were simply endorsing an extreme *laissez-faire* outlook, we would expect that the ratings would pile up in the "Fairly Paid" category expressing approval of the entire range of earnings levels for persons and couples of widely varying characteristics. This outcome is certainly not the case in Table 1. As shown in the last column, about 23% of the ratings are in the "Fairly Paid" category, but the remainder are spread quite widely across the other ratings. Thus, it is clear that the ratings were not randomly distributed among vignettes.

Table 1 may be regarded as a harbinger of tendencies that will emerge illuminated from the regression analyses. For example, the one-person vignettes, which had lower absolute earnings than married couple vignettes, exhibit a strong minor mode at ratings of -4 (Extremely Underpaid) and lower mean ratings, indicating the importance of earnings amount per se. Further, the minor mode is stronger and the mean rating lower for males than for

¹⁰ Following Aristotle (1952: Books II and V), we consider justice to be a mean, a state intermediate to two kinds of injustice—one of excess and the other of deficiency—that are contrary both to each other and to the mean and that are susceptible of degree variation.

Table 2. Regressions of Income Fairness Ratings on Vignette Characteristics: One-Person Vignettes

A. Correlation Matrix, Means and Standard Deviations of All One-Person Vignettes:

	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
Fairness Rating (1)		-.089	-.042	-.079	-.093	-.131	.721	.619

females, regardless of marital status, suggesting that the sex credit is not related to breadwinning.

The structure of judgments about the fairness of earnings. The gross distributions of ratings shown in Table 1 reflect the activity of a number of justice rules. In order to uncover the structure of the justice rules that guided our respondents, we resort to multiple regression as an analytic tool, regressing the ratings on the characteristics displayed in the vignette descriptions. This approach, of course, assumes that a linear, additive relationship exists, which we will test later.

Tables 2 and 3 report the results of these regressions separately for the one-person and the married-couple vignettes. Note that the unit of analysis is the vignette, not the respondent; there are nearly 12,000 vignettes, each of which has been rated by a respondent.

The top panels of Tables 2 and 3 contain the zero-order correlations among the variables used in the regressions reported

in the bottom panels. With the exception of those in the top rows, the correlations are of little interest since they are artifacts of the design of the study, in which vignette characteristics were almost randomly associated with each other. Thus, these correlations are consistently low, a property which enhances the stability of the regression coefficients.

The unstandardized regression coefficients may be regarded as measures of the extent to which each of the vignette characteristics affect the fairness ratings achieved by a vignette. Thus, the coefficient for education (-.0538), in the case of all the one-person vignettes, has a direct interpretation, as follows: for each additional year of schooling attributed to a vignette person, the fairness rating moves .05 of a unit toward the unfairly underpaid end of the rating scale.

A positive coefficient may be interpreted as indicating an increment in the direction of overpayment and a negative coefficient as indicating the direction of

underpayment. Thus, depending on the activity of the whole equation, an increment may equally well indicate decreasing underpayment, a leap to fairness or increasing overpayment. Moreover, the sign of the coefficient also affects the meaning imputed to its magnitude. The larger a positive coefficient, the greater the "penalty," but the larger a negative coefficient the greater the "credit." Thus, as we shall see when we compare raw weights for husband's and wife's characteristics, the larger of a pair of negative coefficients has substantive implications in the same direction as the smaller of a pair of positive coefficients.¹¹

For a variety of reasons, including the claims of economists that the utility of income varies at the margins, we expected to find a nonlinear effect of earnings. Similar reasons led us to entertain the possibility of nonlinearity in the other vignette characteristics. The possibility of nonlinearity in all the independent variables was tested by entering quadratic terms for all the variables into a polynomial regression. Inclusion of second-order terms for all variables except earnings produces increases in the R^2 s ranging from zero to .003, clearly negligible.¹² Quadratic terms for the earnings variables, however, as expected produce increases in the R^2 s that range from .0234 to .0826.

A further search for specific nonlinearities was performed, based on the notion that the income squared term might be masking interactions between earnings and each of the other vignette characteristics. Substantively, such product terms would indicate "separate" evaluations of earnings relative to each attribute. New models were estimated, for all the one-person vignettes together as well as disaggregated by marital status and for all the married-couple vignettes, in which the

fairness rating was regressed on a set of independent variables including all first-order characteristics and all two-way interactions involving earnings. The entire set of product terms increased the resultant R^2 s (from the purely linear models) from .6004 to .6028 in the one-person-single case, from .5720 to .5836 in the one-person-married case, from .5790 to .5887 for all the one-person vignettes together, and from .4758 to .4799 for the married-couples vignettes.

Clearly, the net effects of the product terms are negligible. Such models fail to account for the seven or eight percentage points explained by the income-squared terms (cf. Tables 2 and 3). Moreover, the improvement of one percentage point in the one-person-married case is far outweighed by the costs in interpretation. The product terms are considerably well correlated both with their own constituent terms and with each other (since they share the earnings term).

Thus, we favor a simple additive model of the fairness rating with a single nonlinearity in the earnings term. This model suggests that the basic justice evaluation process implicitly involves three analytic steps: first, the worth of the two earnings terms is calculated; second, the amounts of just remuneration to a set of claims are calculated and summed; third, the sum of the claims is subtracted from the earnings effects to produce the justice evaluation. If the remainder is zero, the individual is judged fairly paid. If the remainder is a positive number, then the individual is judged unfairly overpaid. And, finally, if the remainder is a negative number, then the individual is judged underpaid.

In other words, the best and simplest of these models consistent with the data specifies a straightforward comparison between what an individual of such-and-such characteristics ought to earn and what he/she in fact does earn. This is precisely the model of justice evaluations suggested by Berger et al. (1972).

As Tables 2 and 3 indicate, the vignette characteristics (all of whose coefficients are statistically significant) account for a considerable portion of the variance in the income fairness ratings, ranging from .49 to almost .69. Since the fairness of earn-

¹¹ This activity of the regression coefficients parallels in statistical terms Aristotle's (1952: Book V) observation that "more of the good and less of the evil are gain, and the contrary is loss."

¹² Because of the high degree of freedom associated with the large number of ratings, even these minuscule increases in R^2 produce highly significant F-tests, suggesting rejection of the hypotheses that inclusion of quadratic terms adds nothing to the prediction. However, we consider increases of magnitude less than .01 to be substantively trivial.

ings is being judged, variation in earnings can be expected to consume most of the variation in the fairness ratings. The high earnings effect indicates that, net of everything else, the higher a person's earnings the more likely he/she is to be perceived as overpaid. High earnings per se lead to overpayment judgments, regardless of the income source. The negative coefficients for the earnings quadratic terms indicate decreasing increments in judgments of overpayment, the larger the earned income involved.¹³

The respondents clearly accepted the characteristics we used to describe the fictitious persons as just criteria in earnings allocation. Increments in education, occupation and number of children, as well as maleness and the married state, move judgments toward the underpaid side of the fairness rating scale, suggesting that the justice of earnings is judged not only relative to education and occupation but also to factors extraneous to the occupational sphere.

Looking now at the disaggregated one-person vignettes,¹⁴ the increment in the fairness rating due to the effects of the two earnings terms (first- and second-order) is slightly greater for single than for married persons. The penalty for being female is much higher for singles than for marrieds. Males are viewed as justified in earning more than females, but marriage, and specifically the possibility that the earner supports a household alone, considerably temper this differential.

Turning now to the married-couple vignettes (Table 3), the results indicate that the husband's education and occupation

buy more underpayment than the wife's. When husband's and wife's earnings enter the regression separately, the increment in the fairness rating due to the two earnings terms (first- and second-order) is larger for the husband than for the wife; thus, his earnings contribute a bit more than hers to a judgment in the direction of overpayment. This constitutes the only benefit to women we discern in these data. And, strictly speaking, it is not a benefit "to" women, but rather "through" women to their households.¹⁵

A further search for interactions in the married-couple vignettes revealed one important effect. The product term for the husband's and wife's earnings is highly significant and improves R^2 over two percentage points, or as much as the two earnings-squared terms (cf. Table 3, models [2] and [3]). The coefficient of $-.0029$ indicates a greater justification of the same combined earnings amount when both spouses are employed. For example, the family in which the two spouses each earn \$10,000 has an extra credit of $-.29$ on the fairness rating scale, a credit not granted to the family in which one spouse earns \$20,000 and the other is unemployed. Remember that this effect is net of the effects of absolute level of earnings.

Moreover, this interaction indicates approval of equality of earnings between spouses. For the product term varies inversely with the size of the gap between the factors and is maximized when the two factors are equal. For example, while the spouses who each earn \$10,000 would enjoy a credit of $-.29$ on the fairness rating scale, the family in which one spouse earns \$15,000 and the other earns \$5,000 would have a credit of $-.22$.

Note that the interaction between the two earnings suggests only justification of higher earnings when both spouses are employed and still higher earnings when their earnings are equal. It tells us nothing

¹³ The second-order polynomial is a reasonable, albeit imperfect, approximation of the effect of earnings on the fairness rating. For example, in the married-couple vignettes, the highest mean fairness rating, 2.949 occurs at the combined-earnings value of \$58,000, whereupon the mean fairness rating dips to 1.718 at \$68,000 (mean fairness ratings close to 1.7 also occur at values of 39, 40, 45 and 52 thousand dollars), then recovers to 2.525 at the final combined-earnings value of \$74,000. This activity is represented in our equation by a parabola that peaks at \$64,000 and descends to a combined-earnings effect at \$74,000 which is close to that at \$52,000.

¹⁴ The difference in R^2 due to separate b weights is only .0057 (but statistically significant, as indicated in footnote 12); examination of the differences in the slopes is our main interest here.

¹⁵ As Quevedo y Villegas (1963), the great poet of the Spanish baroque, observed in *Letrilla satirica*: "Poderoso caballero es don dinero," money engenders almost sacred respect. Its presence doesn't ever escape our notice. A family may not get increased prestige for having a wife-mother physician, but it certainly gets judged overpaid if the wife-mother has sizable earnings.

about whether, if there is a gap, it is more tolerable when one spouse rather than the other has the higher earnings.

The Question of Consensus

Although the analyses presented so far have indicated that the linear model is a good fit to the fairness ratings, the R^2 s do not exceed .69, suggesting that there is still some individual variation, some of which may be regarded as "error." Now we consider that consensus exists in a population when there are no significant amounts of structured disagreement among socially recognizable subgroups of the population in question.

In order to search for such structured disagreement, we entered respondent characteristics into the analyses. It should be recalled that since each respondent had an equal chance of receiving each of the vignette samples, the respondent characteristics correlate essentially zero with any of the vignette characteristics. Hence, whatever respondent characteristics affect the ratings do so independently of the analyses presented earlier.

The results of these regressions indicate that the respondent characteristics account for remarkably little of the variance in the fairness ratings. The R^2 values, while statistically significant, are substantively tiny. In the case of the one-person vignettes, all the respondent characteristics together account for only .0045 of the variation in the ratings and, in the case of the two-person vignettes, only .0077. This is strong indication that the determinants of income fairness evaluations are not rooted to any great extent in raters' demographic characteristics.¹⁶

To test the possibility that respondent characteristics interacted with vignette characteristics, we computed all regressions with interaction terms added to the basic set of terms. In no case did the increase in R^2 due to the entire set of interaction terms reach a magnitude of .01.

To explore further a possible effect of sex of respondent on the fairness ratings,

¹⁶ Recall that the ratings were produced by 200 respondents. Hence, the regression results are inflated by intra-individual correlations. So the tiny respondent effects themselves are inflated.

we correlated the mean ratings given by males with the mean ratings given by females for each of the six-hundred distinctly different vignettes. This procedure yielded a correlation coefficient of .9393, highly significant, indicating that the relative orderings given to vignettes by males and by females are virtually the same.

Thus, we conclude that the judgments made by our respondents were guided by consensually held justice rules. The variance left unexplained in Tables 2 and 3 may be attributable to "error" or to characteristics of the respondents on which we have no measures.

Estimating Fair Earnings

We now use the regressions reported in Tables 2 and 3 to estimate the earnings amounts for persons and married couples of varying characteristics that would be most likely to be judged "Fairly Paid." Table 4 reports a number of such estimates for single persons, married persons about whose spouse nothing is known, and married couples. The figures are for individual earnings in the first two cases (the first four columns) and for combined earnings of the married couples.¹⁷

The lowest estimate, \$7,125, is for single females with seven years of education and jobs such as "chambermaid." The highest estimate, \$34,593, is for the combined earnings of a married couple, both college graduates and with jobs such as "lawyer." We suspect that the former estimate exceeds the typical wage for such persons and that the latter figure is less than actual typical earnings for such married couples. These extreme estimates suggest a tighter just distribution of earnings than exists in the empirical world.

Variation within rows reflects the sex and marital status variables. Variation within columns reflects the education and occupation variables. It is clear that

¹⁷ Estimates of fair earnings are obtained by solving according to the quadratic formula the regressions (2) and (3) of Table 2 and (5) of Table 3. The solution sets for each equation contain two real numbers, only one of which lies in the domain of the earnings terms used in this research ($2 \leq x \leq 40$ in the one-person case and $2 \leq x \leq 80$ in the two-person case). It is this one root out of each solution set that constitutes a valid estimate of fair earnings (cf. Kerlinger and Pedhazur, 1973:213-4).

Table 4. Estimated Fair Earnings for Individuals and Married Couples of Varying Personal Characteristics

Education (Years)	Occ. Prestige	Single Male	Single Female	Married Male	Married Female	Married Couple
7	10	\$8,473.70	\$7,125.00	\$9,217.00	\$8,397.50	\$13,187.50
8	10	8,710.50	7,315.80	9,379.40	8,554.60	13,562.50
8	20	9,250.00	7,835.50	10,151.90	9,300.80	15,281.30
8	30	9,815.80	8,375.00	10,950.80	10,070.80	16,937.50
10	20	9,697.40	8,250.00	10,491.00	9,627.90	16,093.80
10	30	10,276.30	8,802.60	11,302.10	10,408.70	17,906.30
10	40	10,868.40	9,355.30	12,144.00	11,216.90	19,781.30
12	30	10,743.40	9,236.80	11,659.10	10,751.70	18,875.00
12	40	11,355.30	9,802.60	12,515.20	11,572.40	20,687.50
12	50	11,986.80	10,388.20	13,407.80	12,425.00	22,687.50
12	60	12,644.70	10,986.80	14,341.80	13,313.60	24,812.50
14	40	11,855.30	10,263.20	12,893.20	11,933.80	21,750.00
14	50	12,506.60	10,861.80	13,802.80	12,801.30	23,812.50
14	60	13,184.20	11,473.70	14,756.40	13,706.70	25,843.80
14	70	13,901.30	12,111.80	15,761.10	14,655.50	28,125.00
16	50	13,039.50	11,342.10	14,205.80	13,184.50	24,812.50
16	60	13,736.80	11,973.70	15,180.40	14,107.80	27,031.30
16	70	14,480.30	12,631.60	16,209.70	15,077.20	29,281.30
16	80	15,250.00	13,328.90	17,304.10	16,100.30	31,812.50
16	90	16,059.20	14,039.50	18,447.80	17,187.40	34,593.80

See footnote 17.

intra-column differences are greater than intra-row differences, suggesting the larger effects of occupationally relevant factors.

The estimates for fair combined earnings are lower than the sum of the earnings of two comparable single persons at the lower attainment levels, but larger at the higher attainment levels. This pattern suggests special credits for low-earnings singles who have to maintain a household alone and also, as noted earlier, for high-earning, both-employed married couples.

The one-person-married condition maximizes earnings across the full spectrum of educational and occupational attainment. We interpret this as a presumed-need differential.

We regard Table 4 as a summary of the region of justice in earnings allocation. Entries in the top row are minimum amounts, and entries in the bottom row are maximum amounts. Differentials between minimum earnings and maximum earnings reflect activity of justly-perceived need and merit factors.

Summary and Discussion

This research shows that the fairness of earnings is judged relative to a set of criteria which includes (but may not be

limited to) education, occupation, sex, marital status and knowledge of family earnings. These criteria appear to be held consensually and are largely independent of the raters' observable demographic attributes.

This means that an equal distribution of earnings would be considered unjust. The justly-perceived dependence of just earnings on earner characteristics suggests a certain inappropriateness of methods for assessing income inequality that have absolute equality as the ideal to be approximated (e.g., Gini's coefficient of concentration and the variance). On the other hand, we certainly found approval for a very restricted variance in the earnings distribution, but this variance must be structured and not random.

One of the more fascinating findings of this research is approval not only of two-earner families, but of a money credit to spouses whose earnings are equal. This suggests acceptance of marital equality as an ideal, and also suggests recognition that married individuals whose spouses are employed work harder and have less leisure than married individuals with unemployed spouses. We think it is time that the tax structure adjusts to the new realities.

There are many questions for future re-

search, but a most important one is to assess the consequences for social systems and for their members of actual earnings distributions that exhibit varying degrees of deviation from the consensually-held principles of justice in earnings allocation.

COMMENTS

PROOF? NO. EVIDENCE? NO. A SKEPTIC'S COMMENT ON INVERARITY'S USE OF STATISTICAL INFERENCE*

(COMMENT ON INVERARITY,
ASR APRIL, 1976)

Inverarity's (1976) selective use of significance tests in his recent study of populism and lynching in Louisiana would seem to require far more justification than provided.¹ In his cross-sectional analysis by parish, goodness-of-fit chi-square tests are applied to entire causal models, but no attempt is made to assess the importance of stochastic processes for individual coefficients. This pattern is all the more curious since significance tests are applied to individual coefficients in the OLS model reported on page 276. Moreover, important substantive conclusions are drawn from the time series shown in Figure 1 with no apparent concern for the alternative explanation of chance. Consequently, even if, as Inverarity argues, the Winch and Campbell (1969) article justifies using goodness-of-fit tests, it is still unclear how it supports Inverarity's decision to consider stochastic processes in some contexts and not others. Therefore, the purpose of this brief comment is twofold: to provide some groundwork for Inverarity's response and to call attention to special issues regarding statistical inference for historical

* Beneath this necessarily brief comment lie a variety of difficult substantive and mathematical issues. To the degree that I have been able to correctly articulate their relevance for historical data, much of the credit belongs to Marilyn Brewer from UCSB's Psychology Department, Thomas Cooley from UCSB's Economics Department, George Bohrstedt from Indiana University's Department of Sociology and an anonymous reader. In addition, much of the background reading for this comment was accomplished over the past year in which my research was, in part, supported by a grant from the Russell Sage Foundation to study methodology for Evaluation Research. Finally, Sarah Fenstermaker Berk deserves credit for the irreverent parts of the comment's title.

¹ Throughout this comment, I will assume that Inverarity means to use a "Classical" approach to statistical inference based on a frequency interpretation of probability. There is certainly no evidence that a Bayesian view was intended: no discussion of prior probability distributions, likelihoods, degrees of belief, and so on (Box and Tiao, 1973).

data (cf. for example, Snyder and Tilly, 1972; Feierabend and Feierabend, 1966; Gurr, 1968).

In an unusually lucid discussion of inferential reasoning, the mathematician Polya (1954:12) characterizes "generalization" as "passing from the consideration of a given set of objects to that of a larger set, containing the given set." This process may be properly undertaken through a wide variety of analytical devices in which chance, as "the ever present rival conjecture," is but one of the many hazards to overcome. In this context, Edgington (1966:485) distinguishes between "statistical" and "non-statistical" inference; the former approached through estimation or hypothesis testing, the latter through "logical" considerations.² My point, therefore, is that Inverarity's selective use of statistical inference per se is not the issue; inferences often may rest on theoretical arguments. However, in the absence of some persuasive rationale, the selective use of statistical inference looks rather like the haphazard use of statistical inference.

Perhaps the most common justification in sociology for statistical inference rests on a hypothetical model in which a very large number of probability samples are independently drawn from a population of *fixed* values and a sampling distribution of the resulting population estimates is constructed (Kish, 1965:9-11). Statistical inference is mandated by a special kind of stochastic "distortion" or "error" introduced by the researcher when only part of a population of fixed values is studied. Each *observation* can be seen as a random variable (Kmenta, 1971:104) and, building on the assumption of a very large number of independent repeated drawings, mathematical-statisticians have provided the techniques with which to estimate from a single sample, the long-run consequences of the sampling process.³

² Under the rubric of what one might call "analytical" or "theoretical" generalization, nonstatistical inferences are made routinely not only in sociological case studies, but in survey research when investigators generalize to units outside the sampled population, both in space and time (Kish, 1965:7-8).

³ I do not mean to imply that the step from an estimated sampling distribution to significance tests and/or confidence intervals is universally accepted. Indeed, there are many lively controversies sur-

However, as Hollis and Nell (1975:76) have observed "statistics does not become a calculus of probabilities either merely by being mathematically sound or merely by being christened a calculus of probabilities." A particular probability calculus must fit the proposed stochastic process and accurately describe the outcomes of its repeated "realizations" (see also Malinvaud, 1970:69-73). Perhaps responding to such considerations, Inverarity's footnote 19 characterizes his data as a "population" (implicitly discarding the random sampling model) and the Winch and Campbell (1969) article is cited as justification for using chi-square goodness-of-fit tests. Unfortunately, this still leaves serious ambiguities.

The random sampling model formally addresses *external validity*: inferences from a probability sample to a population of fixed observations. In contrast, the Winch-Campbell model addresses *internal validity* (Campbell and Stanley, 1966): the degree to which alternative explanations for an assumed causal effect can be ruled out.⁴ Their perspective draws heavily on the randomization process in true experiments by which a researcher attempts to statistically equate groups of subjects (or other units) before the treatment is applied. Subjects are randomly assigned to treatment and control groups so that preexisting systematic differences between individuals are transformed into random *group* differences. While the "luck of the draw" during the assignment process may result in actual nonequivalence (thus confounding treatment effects with "selection" effects), the probability of this occurrence can be gauged with significance tests. Put another way, significance tests reflect the probability over repeated random assignments of the entire subject pool, that what one takes as a treatment effect really results

from chance group differences between experimental and controls (Fisher, 1971:13-4; Lindquist, 1953:11-2).⁵

While the relevance of the randomization model for Inverarity's goodness-of-fit tests may not be immediately apparent, Winch and Campbell (1969) provide the necessary links. To freely translate their somewhat informal discussion, they suggest that regardless of the causal model being entertained, one should also consider a world in which any associations between observed variables are the result of some random assignment process. In other words, social forces replace the researcher as randomizer, and just as one must rule out chance in randomized experiments, one must rule out chance in substantive models. Note that the problem is not random sampling error as described earlier under the random sampling perspective and, thus, not external validity. Rather, the problem is internal validity and ruling out a particular kind of alternative (stochastic) explanation for observed associations.

How well does this model fit Inverarity's cross-sectional data? To begin, footnote 19 is, in fact, broadly consistent with what appear to be Winch and Campbell's central arguments. However, why the model justifies goodness-of-fit tests and not tests of individual coefficients would seem to need further clarification. A random assignment world would appear to warrant the null hypothesis that each of the coefficients are zero. (For some important consequences of this, see Bohrnstedt's adjacent comment.) Then, significance tests would suggest which observed relationships might be understood as random error and which could be attributed to other (deterministic) processes.

More fundamentally, one must also consider how sensible the hypothetical random assignment world really is. Winch and Campbell would seem to require a world that first attaches to each county a value for an endogenous variable and then randomly pairs with it

rounding these inferential procedures which seem a very long way from resolution (Hogben, 1957; Morrison and Henkel, 1970; Barnett, 1973; Bartlett, 1975; Ferguson, 1967).

⁴ This requires some qualification. In the Winch and Campbell (1969) article, the authors were still operating under the Campbell and Stanley (1966) typology. "Instability" was added as a "new" threat to internal validity and resulted from such things as sampling, randomization and unreliable measures. Tests of statistical significance only addressed instability. The revisionist perspective enunciated by Cook and Campbell (1975) treats instability separately as "conclusion validity." In other words, while the issue remains alternative explanations for assumed causal effects, internal validity is reserved for systematic biases while conclusion validity refers to chance factors. And again, tests of statistical significance are only appropriate for the latter.

⁵ While there is wide agreement on the particulars of the randomization models, there is a healthy debate about the appropriate tests when the model is applied to an actual experiment. Subjects and their attached scores on a dependent variable(s) are commonly viewed as randomly shuffled between experimental and control groups (e.g., Siegel, 1956:88-9), but the choice between nonparametric, component-randomization tests and parametric tests is controversial. (Siegel, 1956; Edgington, 1966; Alf and Abrahams, 1972). Regardless of which tests are used, however, all address internal validity and provide no information about generalizations beyond the pool of subjects actually assigned to treatment and control groups.

values for each of the exogenous variables. This entire process is then repeated a very large number of times to generate a "population of realizations" of which the observed data is a single realization. Without such repeated assignments of the full pool of observations, the required sampling distribution on which probabilistic statements necessarily rest is at best imaginary. And while concepts for imaginary things (such as mass in physics) can be useful, they should not be introduced without careful thought and discussion.⁶

Further complications immediately surface when one remembers that, according to the Winch-Campbell model, *the pool of potential observations on all variables is fixed, all marginal distributions remain unchanged in repeated random assignments of the entire pool, and the values of endogenous variables attached to particular counties are constant.* These are substantive statements about a very special kind of randomizing world or, alternatively, about particular historical processes. Why not allow new values on any of the variables to appear in different realizations? Why not allow the marginals to vary? Why not allow values of the endogenous variables attached to particular counties to change? Moreover, the Winch-Campbell model seems only to apply to models with a *single* endogenous variable and thus provides no formal guidance for situations in which the covariance between multiple endogenous variables varies in repeated realizations. In short, the use of the Winch-Campbell model would seem to require far greater justification and may well be inappropriate. Should this be the case, the real meaning of Inverarity's goodness-of-fit tests become obscure. The stochastic processes Inverarity may want to consider are not the ones described by the model.⁷ Exaggerating somewhat, it is a bit like trying to calculate the probability of obtaining a head or tail with a model based on a six-sided die.

⁶ A full-blown Bayesian critique would go a good deal further. Rather than resorting to the mental gymnastics required to conjure up the necessary sampling distribution, the relative frequency approach to statistical inference in this case would be discarded in favor of statistical inference based on "degree of belief" (Barnett, 1973).

⁷ I suspect a better stochastic model could have been developed from econometric traditions (e.g., Malinvaud, 1970:59-61). However, while there is not space here to detail my uneasiness with such models, they in essence seem to define the important problems away through assumptions made about the stochastic processes involved in the "error term" (Berk and Brewer, 1977). The discussion below of time-series models will provide a brief exposure to some of these difficulties.

Turning to the time-series data shown in Figure 1, recall that several important substantive conclusions were reached with no considerations of random processes. Is this reasonable? In fact, stochastic models of longitudinal data may be usefully viewed as another class of randomization models. Each observation is treated as a random variable, the set of observations are treated as a family of random variables, and one can speak about the probability distribution for a given variable or the joint probability distribution for the family of random variables. In addition, when sequential numbers are affixed to each random variable, they represent an equal interval scale describing each observation's location in time. Therefore, each random variable can be treated as a function of time and a wide variety of stochastic models for the relationship between time and the observations may be postulated and tested (Cramer and Leadbetter, 1967; Cinlar, 1975).

Again, internal validity, not external validity is the issue. Each set of observations can be treated as a realization of an underlying stochastic process, not as a random sample from a larger group of time-dependent processes. The stochastic process is typically assumed to be invariant with respect to the displacement of time: the models are assumed to be "stationary" or are transformed into stationary models (Pindyck and Rubinfeld, 1976:435-6).⁸ Each number reflecting an observation's temporal location has meaning relative only to an arbitrary starting point. Thus, one might say that for these models, time has no "historical" interpretation. Or, to quote Nelson (1973:26), "in a probabilistic sense, history repeats itself in a stationary time series."⁹

⁸ At least two qualifications are required here. First, a few kinds of nonstationary models such as the "random walk" can be estimated but, by and large, nonstationarity is removed in social science applications. Second, there are actually many different kinds of stationarity. For example, "strict" stationarity requires that the joint probability distribution be invariant with respect to the displacement of time. "Weak" stationarity only requires that in repeated realizations the expected value of the series is constant, the expected value of squared deviation scores (the variance) is constant and, for any lag, the expected cross-product between random variables (the covariance) is constant. The former implies the latter, but not the reverse (Cramer and Leadbetter, 1967:120-3). For present purposes, however, such distinctions are not critical.

⁹ Technically, one could still speak about external validity to a population of all possible realizations of the stationary series. However, this is, by definition, almost always a substantively trivial population. Thus, interesting generalizations will typically flow from theoretical considerations.

To illustrate: in their introductory chapter to *Stationary and Related Stochastic Processes*, Cramer and Leadbetter (1967) concretize their discussion of stationary processes with an example involving the background "noise" associated with "phase tracking" of satellite transmissions. They display graphs showing that while the temporal series varies from observation to observation, it seems to oscillate around a constant level with fluctuations that seem on the average to be about the same size. Thus, while one requires that the observations be arrayed with real numbers indicating temporal location (e.g., to be able to graph the pattern), one could begin that series at any arbitrary point and expect to find the same patterns were the series to begin at any other arbitrary point. The ordering and spacing of observations is what matters, not the starting point.¹⁰ Consequently, one could take a very large number of time-series samples with each replication treated as an independent realization of the same underlying stationary stochastic process, *even though each realization would necessarily have a different starting point*. This leads to the critical result that a meaningful sampling distribution could be produced from which probabilistic inferences could be drawn.

What happens if the empirical series is, in fact, not stationary? While there is some disagreement on how best to handle nonstationarity (Glass et al., 1975; Hibbs, 1974), there is currently consensus that, for social science applications, one usually interprets its causes as deterministic and attempts to remove them before stochastic models are applied.¹¹ Box and Jenkins (1970) emphasize "differencing" to remove longitudinal trends (e.g., a series shows a gradual increase); econometricians such as Kmenta (1971) and Johnston (1972) emphasize regression techniques. Nevertheless, the statistical inference is still meant to address internal, not external validity.

The implications for Inverarity's time series should now be apparent. If the longitudinal pattern of lynching is viewed as having no stochastic component, conclusions may be drawn with no reference to chance. If the series is viewed as at least partly stochastic and

stationary, then formal estimation procedures may be appropriate. Finally, if the series is viewed as at least partly stochastic and nonstationary, attempts could be made to remove the nonstationarity before estimation. However, such decisions must be made in the context of what numerous replications (or "realizations") *mean* for historical data. The fit between the model of a stationary time series and radio waves, industrial processes and the like seems quite good. The case for patterns of lynchings or other historical events over time would seem far more difficult to make.

In summary, mathematical-statisticians have blessed us with a wide variety of stochastic models which may, in theory, be applied to all manner of social science data. Moreover, these models are often amazingly robust when certain assumptions are violated. However, robustness must not be confused with infallibility if the probability assessments which emerge are to be taken seriously. This means that selection of a particular stochastic model must be carefully made and that one also must determine more generally if stochastic processes, as currently defined, are applicable for the data on hand.

USE OF THE MULTIPLE INDICATORS-MULTIPLE CAUSES (MIMIC) MODEL*

(COMMENT ON INVERARITY,
ASR APRIL, 1976)

In a recent issue of this journal, Inverarity (1976) applies Jöreskog's technique for the analysis of covariance structures (Jöreskog, 1970; 1973) to a Multiple Indicators-Multiple Causes (MIMIC) model of lynchings which occurred in Louisiana in the late nineteenth century. The purpose of this comment is to show that a re-estimation of his parameters indicates that the model for which he suggests support exists probably, in fact, should be rejected.

The basic three-indicator, three-cause model proposed by Inverarity to explain lynchings in Louisiana from 1889-1896 is shown in Figure 1. The structural equation linking the unobserved variable, Mechanical Solidarity (η), to the three exogenous variables, Percent Black (ϵ_1), Urbanization (ϵ_2) and Religious Homogeneity (ϵ_3), is given by

$$\eta = \alpha_1\epsilon_1 + \alpha_2\epsilon_2 + \alpha_3\epsilon_3 + \epsilon, \quad (1)$$

* The author is grateful to Richard Berk, William Bielby, Peter Burke, Arthur Goldberger, Robert Hauser and Michael Hout for helpful comments on an earlier draft of this comment. As usual, the author takes sole responsibility for any errors. Special thanks to Debbie Adams for typing the manuscript.

and the measurement model linking the three indicators, Percent Democratic Vote, 1892 Presidential Election (y_1), Percent Democratic Vote, 1896 Gubernatorial Election (y_2) and Lynchings, 1889–1896, to Mechanical Solidarity are

$$\begin{aligned} y_1 &= \beta_1 \eta + u_1 \\ y_2 &= \beta_2 \eta + u_2 \\ y_3 &= \beta_3 \eta + u_3 \end{aligned} \quad (2)$$

where α_1 , α_2 , α_3 , β_1 , β_2 and β_3 are the primary parameters of interest to be estimated.¹ Using the more compact matrix notation where y and x are 3×1 vector of observables, α and β 3×1 vectors of coefficients and u a 3×1 vector of error terms, Hauser and Goldberger (1971) and Jöreskog and Goldberger (1975) show that substituting (1) into (2) yields

$$\begin{aligned} y &= \beta(\alpha'x + \epsilon) + u \\ &= \pi'x + v \end{aligned} \quad (3)$$

which is the reduced form where $\Pi = \alpha\beta'$ is the coefficient matrix and

$$v = \beta\epsilon + u \quad (4)$$

is the reduced form disturbance vector. The covariance matrix of v is

$$\Omega = E(vv') = \sigma_\epsilon^2 \beta\beta' + \Theta^2, \quad (5)$$

where Θ^2 is diagonal. Jöreskog and Goldberger (1975:632) point out that the reduced form parameters remain unchanged if β is multiplied by a scalar and α and σ_ϵ^2 are divided by the same scalar. Some decision must be made about how to resolve this indeterminacy. Jöreskog and Goldberger chose to assume that the variance of ϵ is unity, i.e., $\sigma_\epsilon^2 = 1.0$ although, as we shall see, other decisions which fix the metric of the unobserved variable are also possible.

In attempting to reproduce the results Inverarity presented in his Figure 3, we first fixed σ_ϵ^2 to unity, but the estimates obtained varied from those presented by Inverarity in some unexpected ways.² Table 1 shows the results of

† See text for an explanation of differences between Inverarity's and our estimates.

both Inverarity's and our analyses. First, note that Inverarity's estimates of the α_i are roughly .743 smaller than ours, and the β_i roughly 1.346 times larger than ours. Notice that .743 is Inverarity's estimate of the variance of ϵ and that if one multiplies our β_i by .743 and the α_i and σ_ϵ^2 are divided by .743 that the two sets of estimates are roughly equal, as one would expect given the indeterminacy discussed earlier. Apparently, Inverarity attempted to estimate σ_ϵ^2 rather than fixing it *a priori* and ACOVS, as it will do, provided an answer even though the model is not identified.³ Somewhat curiously, he has the correct degrees of freedom—six, instead of the five one would expect if he indeed tried to estimate σ_ϵ^2 . In reporting the standard deviations of the u_i , Inverarity apparently mistook the standard deviations the program printed for variances, since his estimates are the square root of ours except for rounding error.

By themselves, these differences would hardly be worth the fuss. Much more important is Inverarity's failure to report the standard errors of estimates.⁴ As Malinvaud (1970:60)

³ In trying to replicate Inverarity's results, we estimated σ_ϵ^2 instead of fixing it at unity. While we failed to replicate his results, we were able to generate yet another set of estimates for the α_i and β_i which satisfy the data equally well, further illustrating the indeterminacy of any solution without making some assumption about σ_ϵ^2 . We also thought that he might have used a procedure described by Werts et al. (1973) which combines maximum likelihood and least squares estimates, but we could not reproduce his results with this technique either.

⁴ In fairness to Inverarity, it must be pointed out that some versions of ACOVS, in particular ACOVSS and ACOVSL, do not compute the information matrix necessary to obtain the standard er-

¹ The notation used in this comment is that of Jöreskog and Goldberger (1975) rather than that of Inverarity.

² All of the results presented in this comment were estimated using LISREL (Jöreskog and van Thillo, 1972). However, the results shown in Figure 1 were reproduced exactly using ACOVSF (Jöreskog et al., 1970), guaranteeing that our results do not differ from those of Inverarity as a function of having used LISREL instead of ACOVS. We, personally, find MIMIC models of this sort easier to set up using LISREL.

points out, the use of tests of significance is justified on one of two bases:

On the one hand, the phenomenon to be studied may be considered to resemble a process entailing random determination of certain quantities which are in this case assumed to be random in the universe as well as in the observed sample. On the other hand, the individual observations may be selected at random in which case the sample is random in composition and therefore the data are also random even if they refer to non-random quantities.

We shall always adopt the first position. The stochastic model will be supposed to represent the process which generates the quantities studied.

On the assumption that Inverarity views the relationship between boundary crises, Mechanical Solidarity and repressive justice as a general social process, the use of significance tests with his sample of 59 Louisiana parishes seems appropriate even though these cases are not a random sample from some larger population.⁵

In Figure 1, we present re-estimates of Inverarity's Figure 3 in which we have rescaled the variance of η , the unmeasured variable, to equal unity. This rescaling means the entire solution is standardized and, hence, simplifies interpretability. In addition, the standard errors are presented in parentheses alongside the coefficients. Notice that neither the coefficient linking Urbanization (ξ_2) to Mechanical Solidarity (η) nor that linking Religious Homogeneity (ξ_3) to it is large enough to reject the null hypotheses, calling into question whether Urbanization and Religious Homogeneity properly can be thought of as causes of Mechanical Solidarity, even though a chi-square test suggests that the overall fit of the data to the model is reasonably good.

To further test the adequacy of this model, Inverarity (1976:276) poses an alternative model where Black Population Size is allowed to affect lynchings directly, in effect to "test whether the estimates of the first model are spurious." The results obtained lead Inverarity to conclude that the inclusion of Black Population Size in the model does, in fact, reduce the

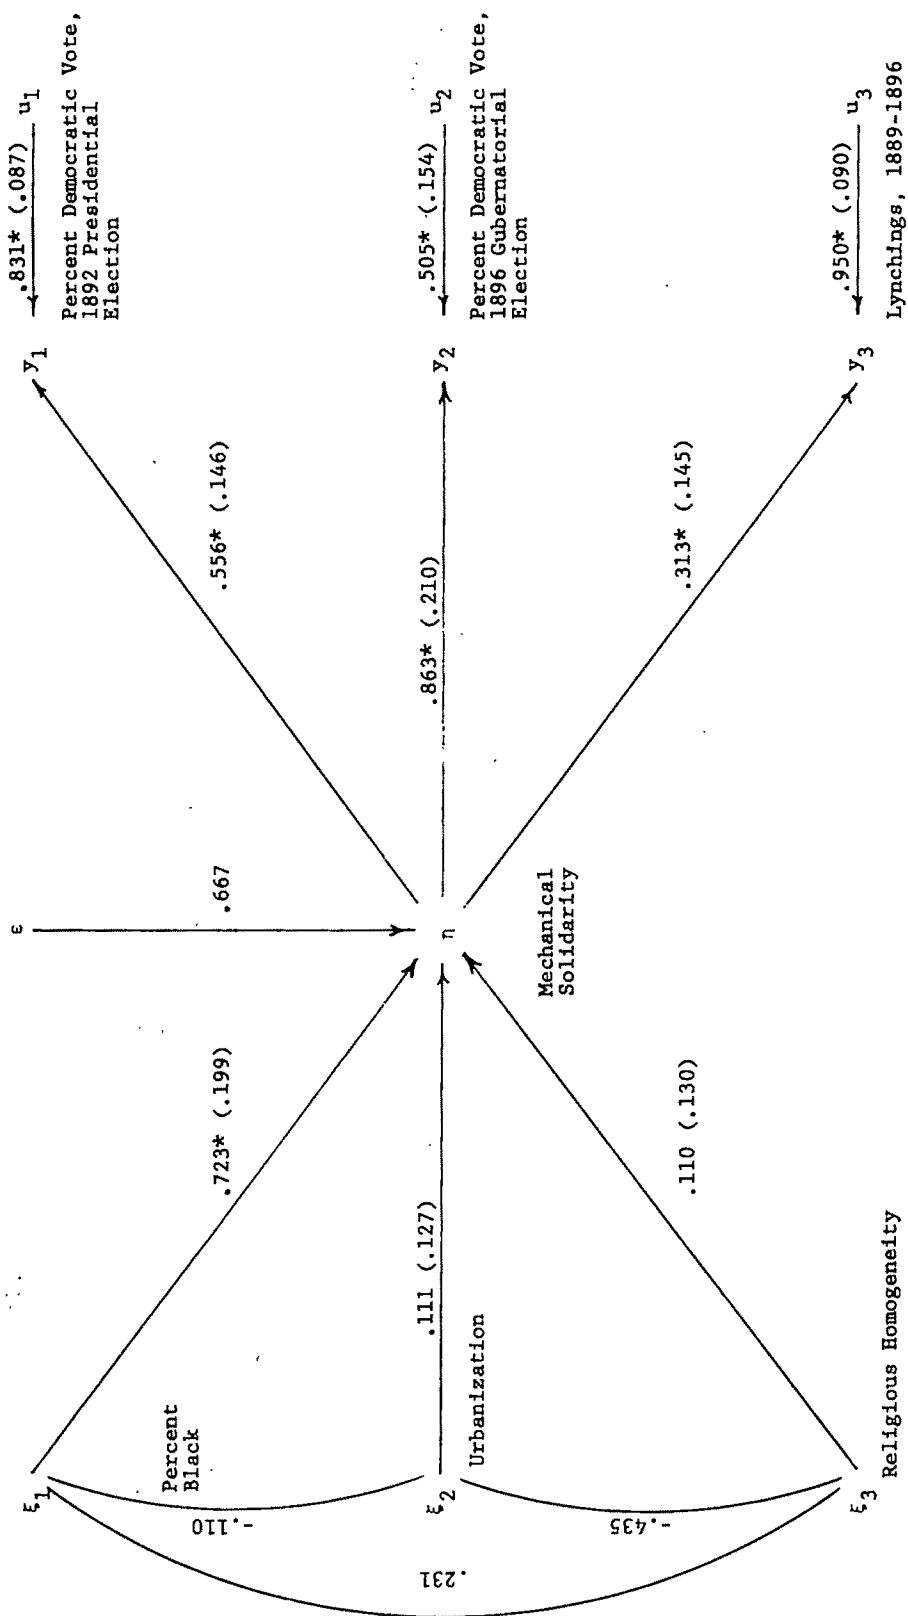

effect of Mechanical Solidarity on lynchings, but since some effects due to Mechanical Solidarity remain, Inverarity accepts the results of the analysis as providing additional evidence for the hypothesis that the degree of repressive justice is affected by the level of Mechanical Solidarity. However, our reanalysis of Inverarity's alternative model seriously calls this conclusion into question, since the path from Mechanical Solidarity is not statistically significant (see Figure 2).

What model might adequately explain the data? One alternative which utilizes the findings of the models already re-estimated is shown in Figure 3. While Inverarity's alternative model (his Figure 4) included Black Population Size, we have omitted this variable since it is also the numerator of Percent Black which guarantees a conceptual and mathematical dependency. A discussion of this problem can be found in Fuguitt and Lieberman (1974) and Schuessler (1974). Overall, the model shown in Figure 3 fits the data reasonably well ($\chi^2_2 = 3.68$, $p = .16$) although the correlation between Percent Black and Lynchings implied by the model is .202 whereas the observed correlation is .295 leaving an unexplained residual of -.093. Note that Mechanical Solidarity does have a small, but statistically significant coefficient linking it to Lynchings.

A natural, plausible alternative to the immediately previous model posits a direct path from Percent Black to Lynching. The data Spilerman (1970) presents on racial disturbances in the 1960s certainly suggests the plausibility of this alternative model. The results for this alternative model, shown in Figure 4, are unfortunately equivocal. The direct path from Percent Black is much larger than the path from Mechanical Solidarity to Lynchings. Specifically, the direct effects are .267 and the indirect effects through Mechanical Solidarity are only .028, seriously calling into question the need for Mechanical Solidarity as an intervening variable. But the standard error associated with the direct path is too large (.168) to allow one to reject the hypothesis that this parameter is in fact zero. Alternatively, the improvement in fit as assessed by a χ^2 test with one degree of freedom is marginal since $\chi^2_1 = 1.84$, significant at only the .20 level. But there is no question that *all* of the analyses suggest that Mechanical Solidarity as measured in this study, at best, has no more than a small effect on lynchings in Louisiana in the late nineteenth century. Indeed, the most obvious alternative is that Percent Black is the only variable one needs to explain lynching in these data, although it is our preference to let those who are

rors. We do not know which version was available to him. It is also the case that if a model is not identified, then the inverse of the information matrix cannot be taken and the standard errors would not be estimable (Wiley, 1974), a condition which will obtain if one attempted to estimate σ^2_η , instead of fixing it.

⁵ For a more detailed discussion of the issue of statistical significance using historical data, see the adjoining comment by Berk.

* Estimate is at least twice the size of its standard error. Standard errors in parentheses.

closer to this substantive area argue the merits of this alternative explanation.⁶

This exercise in model building has assumed the correctness of Inverarity's claim that Percent Black is a cause of Mechanical Solidarity and that the two measures of Democratic vote adequately reflect it. To the degree that these assumptions can be questioned, the substantive conclusions drawn above may have to be altered.

REPLY TO BAGOZZI, BERK, BOHRNSTEDT, POPE AND RAGIN, AND WASSERMAN

The five comments that have appeared in recent issues of this journal correct and elaborate several ideas in the original article, and raise several issues that merit further discussion. Due to space limitations, however, I will restrict my reply to the following three issues, which seem to me in greatest need of clarification: (1) the relationship between the theories of Durkheim and Erikson; (2) the operational definitions employed by the article; (3) the role of significance tests in historical investigation.

Erikson versus Durkheim

First, Pope and Ragin's confusion over the relationship between Durkheim's thesis and Erikson's reformulation¹ requires a brief re-

¹ Erikson's (1966) point of departure is Durkheim's parable of the community of saints, in which repressive justice persists even though the community consists entirely of individuals leading exemplary lives (Durkheim, 1950:67-9). The moral of the parable, Erikson points out, is that punishment is the consequence of exigencies of community organization. Variation in those exigencies are the focus of Erikson's concept of *boundary crises*. There is, thus, much greater continuity between Erikson's study and Durkheim's theory than Pope and Ragin seem to recognize. It is, however, true that Erikson does not address many of the issues posed by Durkheim in his discussion of law and social structure (e.g., the evolutionary development thesis), and Pope and Ragin quite legitimately chastise my article for being too elliptical in discussing the relationship between the two.

⁶ Black Population Size would seem to be an even better choice as an exogenous variable since its zero-order correlation with lynchings is .418 compared to .229 for Percent Black.

statement of the purpose of my article. In *Wayward Puritans*, Erikson (1966: 5) set about "to see if [Durkheim's] insights can be translated into useful research hypotheses." Lost in the translation was the distinction between mechanical and organic solidarity. My article reintroduces this distinction because:

some actions . . . are more strongly repressed than they are reproved by general opinion [The state can become] an autonomous factor in social life . . . [defining] as criminal actions which shock it without, however, shocking the collective sentiments in the same degree. (Durkheim, 1964: 82-3)

Under what conditions will repressive justice be independent of collective sentiments? Durkheim (1964) provides no coherent answer² and Erikson (1966:9) bypasses the problem altogether, asserting that boundary crises and crime waves are universally associated. My article (Inverarity, 1976:263) questions this assumption on empirical grounds. Since this question is central to my analysis, let me belabor it briefly. I suspect that Erikson's argument could not be applied to crime waves in Massachusetts after the seventeenth century when that society moved from being a relatively homogeneous theocracy to a complex society characterized by occupational differentiation, denominational pluralism and ethnic diversity (see, e.g., Thernstrom, 1969:33-56). In the latter type of society, some actions are more likely to be strongly repressed than strongly reproved and, consequently, we could not expect any systematic relationship between crime waves and boundary crises. In general, attempts to apply Erikson's analysis to modern nation-states (e.g., Blumenstein and Cohen, 1973) are, from this standpoint, essentially misguided. My article seeks to formulate the general conditions under which boundary crises and crime waves are related by reconsidering Durkheim's distinction between mechanical and organic solidarity. In particular, the article attempts to formulate the issue empirically, conceiving of communities as varying in degree of mechanical solidarity. In communities with a low degree of mechanical solidarity (e.g., seventeenth-century Virginia), repressive justice will have little to do with collective sentiments, and boundary crises will

tend to be unrelated to crime waves. In communities with a high degree of mechanical solidarity (e.g., seventeenth-century Massachusetts), repressive justice will be closely linked with collective sentiments and, as Erikson (1966) demonstrates, crime waves vary systematically with boundary crises. The ideal research setting in which to test this argument would be one in which a number of diverse, yet comparable communities face a single boundary crisis. Unfortunately, Clio seldom provides for research designs so we are forced to make do with approximations. Such an approximation for our present problem can be found in the relationship between the solidarity among Southern whites and their propensity to lynching during the 1890s. Several of the comments raise serious questions over how good an approximation this period actually provides.

Operational Definitions

Specifically, the comments question the following equations made in the article: (1) lynching = repressive justice; (2) Solid South = mechanical solidarity; (3) Populist revolt = boundary crisis.

Lynching and repressive justice. Pope and Ragin reject the equation of lynching with repressive justice because, in most cases, white mobs lynched black victims and it is written (Durkheim, 1964:73) that a community imposes repressive justice on "those of its members" who offend the collective conscience. Since black victims are not members of the white community, the lynchings of blacks *ipso facto* cannot be legitimately interpreted as instances of repressive justice. Such lynchings are, rather, instances of "intergroup sanctions."

While Durkheim's discussion of repressive justice typically does deal with cases in which a member of the group is singled out and punished for some offense committed, the transformation of an insider into an outsider is not a universal characteristic of repressive justice.³ For example, Durkheim (1964:85-6, 90) writes:

punishment consists of a passionate reaction. This character is especially apparent in less cultivated societies. In effect, primitive people punish for the sake of punishing. . . . It is thus that they punish animals which have committed a wrong act, or

² This issue arises only *en passant* in *The Division of Labor*, but Durkheim (1973) later elaborated on this qualification, introducing centralization of political power as a limitation on the conditions under which repressive justice is related to mechanical solidarity. This theme is not explored here; for some suggestive discussion of secular trends in agencies of capital punishment, see Bowers (1974:40).

³ Pope and Ragin suggest further that the punishment of outsiders falls more properly into Simmel's conceptual balliwick, overlooking the possibility that Simmel and Durkheim, at several points, are addressing the same phenomenon in different terminology (cf. Coser, 1961; Scott, 1976).

even inanimate beings which have been its passive instrument . . . [In more cultivated societies, punishment is] more clarified, it expands less on chance. One no longer sees it turn against the innocent to satisfy itself.

The object of repressive justice may, thus, be neither a member of the group nor objectively guilty. The *sine qua non* of repressive justice is not the object of punishment, but the diffuse, passionate, ritualistic character of the reaction against an alleged offender. This point is of particular importance for Erikson and others who subscribed to some version of the labeling approach to deviance. Central to the labeling orientation is Durkheim's discussion of crime as a consequence of punishment and suggestion that the instigation of repressive justice lies not in the nature of the criminal act, but in the exigencies of the social system (see, e.g., Bordua, 1967).

Wasserman's objection to equating lynching with repressive justice rests more on empirical than exegetical grounds. Following Tilly's (1975) thesis that collective violence is often a consequence of collective action undertaken by political actors to gain or maintain their position in the polity, Wasserman contends that the increase of lynching in the 1890s could be explained as a consequence of the disfranchisement battles during this period. He then attempts a crucial test between my argument and the implications of Tilly's general formulation by comparing the impact of the Populist contest with the impact of the disfranchisement controversy on lynching.

It is not clear to me, however, how his test can be used to decide between a boundary crisis and a political contest interpretation of lynching episodes. First, it is not clear why the Populist revolt could not be considered a political conflict in Tilly's terms. A major issue for the Populists was the political representation of the class interests of lower-class whites. On the other hand, the disfranchisement controversy can be viewed as a manifestation of the boundary crisis of the Solid South. The theoretic frameworks of both Erikson and Tilly would account for an increase in lynching as a consequence of the political crisis in the South during the 1890s. Both formulations, it seems to me, would take the Populist revolt and the disfranchisement movements as indicators of the political crisis. The difference between the two theoretic formulations lies more in the processes by which political conflict is displaced into forms of violence, which may themselves be manifestly apolitical (e.g., food riots). Adjudicating between the two explanations will require a greater elaboration of the theories than Wasserman presents and prob-

ably more refined data than either of us has presented so far.

The Solid South and mechanical solidarity. Pope and Ragin contend that it is inadmissible to operationalize mechanical solidarity as solidarity among post-Reconstruction Southern whites because of the presence of conflict and the absence of complete homogeneity among Southern whites. The connection is problematic, but their objections are not particularly cogent.

Pope and Ragin's rough content analysis of my article reveals six references to "conflict" or its cognates in the discussion of the Solid South.⁴ Unfortunately, this juxtaposition of events ignores the main theme that after Reconstruction there was a period in Louisiana and throughout the South in which race and region became the focus of identification and political activity. The consensus was by no means total and its extent has been overstated by some historians. Nevertheless, an unprecedented level of solidarity among Southern whites after Reconstruction made Louisiana a very different type of differentiated society than, say, Massachusetts of the same period. Furthermore, the Populist revolt was experienced in certain states as a major social earthquake, to reiterate Carl Degler's metaphor, constituting what can be characterized in Erikson's terms as a boundary crisis. In short, white solidarity was not nominal, and the presence of conflicts and contradictions in the society of white Louisiana no more invalidates the applicability of Erikson's argument to this setting than the presence of conflicts and contradictions invalidates the applicability of his argument to Puritan Massachusetts.

The second major objection is that while mechanical solidarity is characteristic of undifferentiated societies, the white population of Louisiana in the 1890s is highly differentiated. For mechanical solidarity to be present among Louisiana's whites, one would have to claim

⁴ Some of the misgivings of Pope and Ragin appear to be motivated by a conflict versus consensus orientation toward social theories. For them, the presence of conflict "brings to mind the Marxian image of class conflict or the Weberian image of competitive advantage between and among classes" (cf. Chambliss, 1976). I find myself more inclined toward Giddens's (1976:717) position that the conflict-consensus dichotomy has outlived its usefulness and tends to hinder analysis. Indeed, one of the virtues of Erikson's study is that it transcends this dichotomy, showing how the structural contradictions in Puritan society produce episodes of repressive justice as attempts to redefine moral boundaries.

that "Southern whites were all alike and exhibited [a] lack of individuality" (Pope and Ragin 1977:364).

To be sure, not all white Louisianans had the same occupation; not all belonged to the Baptist Church, the Masons, or the United Confederate Veterans. But does such heterogeneity preclude the characterization of such a society as mechanically solidary? Durkheim (1950:83), after all, points out that the horde, consisting of undifferentiated individuals, is an ideal type, "the protoplasm of the social realm, the natural basis of classification. It is true, perhaps, that no society corresponds to this description." Using the criterion proposed by Pope and Ragin, *mechanical solidarity* could never be applied to any historical society. The real issue is a much more subtle one: whether the solidarity among Louisiana's whites is of a nature and extent that can be characterized adequately as mechanical. Pope and Ragin feel that it cannot, but the question must be determined on a more explicit assessment of the historical evidence.⁵

Populist revolt and boundary crisis. Pope and Ragin identify a serious equivocation in the original article's (Inverarity, 1976:264) statement that "election statistics provide . . . an index of the extent of variation in boundary crises." This makes the subsequent use of percent Democratic vote as an index of solidarity puzzling. The intended meaning of this statement was that (1) the occurrence of elections would be the focal points of the boundary crisis and (2) the magnitude of the boundary crisis could be approximately gauged by the magnitude of the Populist vote *among states*. Underlying this perspective is the idea that counties in the same state all experience a common

boundary crisis by virtue of the fact that states are the principal foci of political organization—parties are formed at the state level and most of the major political offices (including Presidential electors) are chosen at the state level. This means that a parish which is 100 percent Democratic would be threatened by Populism as much as a 50 percent Democratic parish. The occurrence of elections, then, can be used as indices of variation in boundary crises, while the percent Democratic vote *within* a parish could be used as an index of solidarity.

Role of Significance Tests

Finally, I would like to make some very brief observations on Berk's (1977:675–6) important critique of the use of significance tests with nonexperimental data. Berk is quite correct in arguing that the use of such tests ought not be perfunctory and more care should have been taken in my article in specifying the meaning of such a test for these data. I introduced the goodness-of-fit test as *one* alternative plausible explanation for the observed pattern of relationships. Such a test can best be conceived as a simple counterfactual model (see McClelland, 1975:146–68). Such models have fairly widespread use in econometric history where they generate the same fundamental objections over the utility of hypothetical conclusions drawn on the basis of highly questionable assumptions.

Conclusion

The specification and estimations of my causal models have been corrected by Bagozzi (1977) and Bohrnstedt (1977). The upshot is that percent black is the only significant causal variable and that one could dispense with mechanical solidarity as a cause of lynchings by allowing percent black to affect lynchings directly. These results are not surprising since almost all studies of race relations find racial composition as the overriding independent variable (cf. Spilerman, 1970). The basic problem for those interested in doing research in this area is that percent black is a proxy variable; moreover, it is a proxy variable for a number of different processes. Consequently, a major task in any future analyses of lynching will be to develop models and locate indicators that make it possible to interpret meaningfully the statistical effects of racial composition.

Finally, I would like to thank the authors of these comments for locating errors in the origi-

⁵ Another exegetical objection is that mechanical and organic solidarity have an unilinear evolutionary relationship in Durkheim's work and "Durkheim did not portray societies as rapidly fluctuating in and out of mechanical status" (Pope and Ragin, 1977:363). He had no particular reason to do so, since such fluctuations are atypical. But they do occur. Such a regression occurred among Southern whites after Reconstruction. More generally, disasters are often followed by a "resurgence of mechanical solidarity" in communities (Turner, 1967). Along similar lines, Durkheim (1965:244–5) treats the civic religion of the French Revolution as an atypical resurgence of mechanical solidarity but one useful for analysis of social processes. In short, the typology (mechanical-organic, segmental-differentiated, repressive-restitutive) is not treated by Durkheim quite as rigidly as Pope and Ragin suggest (cf. Durkheim 1964: 105n); moreover, such a rigid construction would render Durkheim's ideas inapplicable to any empirical context.

nal article and helping me to clarify my analysis. I hope to give a more extended and adequate treatment to the issues discussed here in my future work.

STRUCTURAL CONTROL MODELS OF ORGANIZATIONAL CHANGE: A REPLICATION AND CAVEAT *

(COMMENT ON HUMMON, DOREIAN AND TEUTER, ASR DECEMBER, 1975)

In a recent paper, Hummon, Doreian and Teuter (1975) introduced a methodology which we believe represents a promising advancement for the study of organizational development. With it, the authors purport to have captured the dynamics by which "all components of organizations influence the change of all other components" (Hummon et al., 1975: 816). Hummon et al. test the

* Authors' names are listed alphabetically. Data collection was supported by the Center for the Management of Public and Nonprofit Enterprise, Graduate School of Business, University of Chicago. Data analysis was supported by the School of Graduate Studies, Queen's University.

model with data originally collected by Meyer (1972). These data are from a sample of 194 finance departments and include size of production component (P), size of supervisory component (S), number of divisions (D) and the number of levels (L) for both 1966 and 1971. The major short-run structural effects identified by Hummon et al. are summarized in Figure 1. The substantive findings are somewhat unexpected because organization size, which is closely represented by P, does not appear to have the unidirectional influence on other structural variables found in earlier studies (Meyer, 1972; Blau, 1970). The four structural characteristics are interdependent in a very complex manner, and D and L, which represent horizontal and vertical differentiation, have a substantial direct influence on P.

There is every likelihood that additional longitudinal studies of organizations will be undertaken in the future and that the use of such control models will increase. Thus we undertook to replicate the Hummon et al. procedure in order to test the method and to learn whether the unexpected structural influences are characteristic of a separate sample of organizations. We find that the method appears to have great potential for organization studies. However, during the replication we encountered problems which indicate to us that the particular model used by Hummon et al. may not be sufficiently well specified to yield valid results.

Replication

The structural control model developed by Hummon et al. involves three major assumptions.

Assumption 1. There is some optimal value for each organization component, P, D, S and L, at each point in time. These values

may be represented by a four-dimensional vector, X^* , where

$$X^* = \begin{bmatrix} P^* \\ D^* \\ S^* \\ L^* \end{bmatrix}.$$

Assumption 2. The optimal value for each organization component may be approximated as a linear function of the actual values of the other organization components. In other words, the optimal number of administrators is a function of the actual number of production workers, levels and divisions; the optimal number of divisions is a function of the actual number of administrators, levels, and production workers, and so on. This system may be expressed as

$$X^* = AX + B \quad (1)$$

where

$$A = \begin{bmatrix} 0 & a_{12} & a_{13} & a_{14} \\ a_{21} & 0 & a_{23} & a_{24} \\ a_{31} & a_{32} & 0 & a_{34} \\ a_{41} & a_{42} & a_{43} & 0 \end{bmatrix}$$

$$\text{and } B = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \\ b_4 \end{bmatrix}.$$

As we shall see below, this is the most critical assumption. By defining each optimal organizational characteristic as a function composed solely of other internal organizational variables, the organization is treated as a closed system. The authors specifically exclude external variables from their structural control model (p. 815). The model does not allow for environmental changes and, therefore, contains no explanation for what shocks the structural components out of equilibrium in the first place. Furthermore, if the model is stable, each component will move toward its optimal value and come to rest in a stationary state.

Assumption 3. The difference between the optimal and actual values for organization components causes a change in the structural components. For example, if the actual number of administrators is below the optimal level, the organization presumably will add administrators. These adjustment mechanisms can be represented by the following differential equation system:

$$\dot{X} = C(X^* - X) \quad (2)$$

Figure 1. Major Short-Run Dynamic Influences in Finance Departments (Hummon et al.: 821)

where

$$C = \begin{bmatrix} c_1 & 0 & 0 & 0 \\ 0 & c_2 & 0 & 0 \\ 0 & 0 & c_3 & 0 \\ 0 & 0 & 0 & c_4 \end{bmatrix}$$

$$\text{and } \dot{X} = \begin{bmatrix} dP/dt \\ dD/dt \\ dS/dt \\ dL/dt \end{bmatrix}$$

Substitution of (1) into (2) yields the result that short-run structural adjustments may be represented in terms of the actual organizational profile at each point in time. That is,

$$\dot{X} = C(A - I)X + CB \quad (3)$$

or, as Hummon et al. express it,

$$\dot{X} = QX + r \quad (4)$$

where

$$Q = C(A - I), \text{ and } r = CB. \quad (5)$$

We fitted the structural control model in precisely the same fashion as Hummon et al., using data from a sample of 92 Illinois high school districts. Data for 1965 and 1970 were collected from annual reports filed with the Illinois State Superintendent's Office. The specific measures used were:

Size of Production Component (P) = Number of Teachers (1965: $\bar{X} = 103.9$, S.D. = 92.2; 1970: $\bar{X} = 140.6$, S.D. = 132.2).

Size of Supervisory Component (S) = Number of superintendents, principals, assistants, supervisors, coordinators and business managers (1965: $\bar{X} = 5.8$, S.D. = 7.1; 1970: $\bar{X} = 10.8$, S.D. = 12.4).

Number of Levels (L) = Number of hierarchical levels between superintendent and teachers (1965: $\bar{X} = 3.2$, S.D. = 1.0; 1970: $\bar{X} = 3.6$, S.D. = 1.1).

Number of Divisions (D) = Number of occupational specialties extant in the district (1965: $\bar{X} = 6.7$, S.D. = 2.4; 1970: $\bar{X} = 7.3$, S.D. = 2.8).

Our coefficient estimates for the optimal structure, $X^* = AX + b$, are¹

$$A = \begin{bmatrix} 0 & 0 & -434 & -705 \\ 0.053 & 0 & -0.369 & -0.213 \\ 0.261 & 0 & 0 & 0.448 \\ 0.0056 & 0 & -0.013 & 0 \end{bmatrix}$$

$$\text{and } B = \begin{bmatrix} -0.0214 \\ 1880 \\ 3.96 \\ 5.20 \end{bmatrix}$$

¹ The data for intermediate computations are available upon request.

Our estimates for the short-run dynamic adjustment model, $\dot{X} = QX + r$, are

$$Q = \begin{bmatrix} 0.00862 & 0 & 3.75 & 6.08 \\ 0.0379 & -0.719 & -0.265 & -0.153 \\ 0.133 & 0 & -1.11 & -0.497 \\ 0.00215 & 0 & -0.0049 & -0.384 \end{bmatrix}$$

$$\text{and } r = \begin{bmatrix} 0.0947 \\ -16.7 \\ 2.09 \\ 3.27 \end{bmatrix}$$

In Figure 2, we summarize the major short-run features of structural change in our sample, which may be compared with the Hummon et al. findings in Figure 1. The high school districts appear to behave quite differently from the finance departments. Our results are closer to traditional findings because P (size of production component) is the major causal variable. All other variables in the system respond to changes in P. The effect of P is not unidirectional, however, because L and S have reciprocal effects upon P. In the finance departments (Figure 1), D appears to be the major causal variable, while D has no significant influence on other variables in the high school sample. The other major difference between the two sets of organizations is the lack of negative feedback within P of the high schools.²

² One of the eigenvalues of our system is slightly positive. Mathematically, this implies instability. It is interesting to note, however, that Hummon et al. (p. 818) were on the verge of a similar result.

Figure 2. Major Short-Run Dynamic Influences in High School Districts

Specification Problems

The differences in short-run adjustments for the two sets of organizations are of secondary importance at this point. We suspect that major structural effects in both models may have been induced by specification constraints. As Hummon et al. (p. 817) show, stability conditions must be met for a satisfactory dynamic interpretation of the results. But the requirement of stability itself has disturbing implications. If the model is stable, the short-run structural changes for each organization follow a trajectory toward a *fixed* optimal structure given by

$$X^{\infty} = (I - A)^{-1}B. \quad (6)$$

Furthermore, since (1) is assumed to hold for all structures, then it must also be true when the organization has its optimal structure. In which case, we may write $X^* = AX^* + B$, or

$$X^* = (I - A)^{-1}B. \quad (7)$$

From the equality of (6) and (7), we see that Hummon et al.'s assumption of a closed organization system implies that the actual structure gradually (but surely) converges to a fixed optimal configuration, with the *same* number of administrators, production workers, levels and divisions for *each* organization.³ This is surely unreasonable *a priori*, because one does not typically perceive organizations as making short-run adjustments solely to reach identical, fixed configurations. Furthermore, the computed optimal structures for finance departments and high schools (Table 1) contain other anomalies. Some optimal values are impossibly large while others are negative. One might question the validity of the short-run structural influences in Figures 1 and 2, when these influences are presumably moving each organization toward the unlikely optimal values of Table 1.

³ This follows directly from (6) and (7) and the fact that matrices I , A and B involve only constants.

Table 1. Projected Steady State (Optimal) Structures for Finance Departments and High School Districts

Component	Finance Departments	High School Districts
$P^{\infty} = P^*$	355	-54.5
$D^{\infty} = D^*$	-21.8	1879
$S^{\infty} = S^*$	39.5	-8.00
$L^{\infty} = L^*$	0.138	5.00

Hummon et al. are aware of the long-run optimal values, but deny that the organizations are moving toward those values (p. 819). This denial, however, appears to contradict their stability findings (p. 818). We certainly agree that the organizations are not actually evolving toward a fixed optimal structure. The problem is that the observed short-run structural control mechanisms behave as if each organization structure is moving toward fixed optimal values. It does not seem meaningful to consider the short-run outcomes of the model and ignore the long-run outcomes.

As it stands, this model creates a double bind for the user. If the requirement of stability is not met, then the findings assume that organizations can grow without bounds. If the requirement of stability is met, then the findings assume that all organizations are moving toward an optimal stationary state. Neither outcome is satisfactory.

Suggested Solution

The problem with the structural control model, as it now stands, lies with Hummon et al.'s assumption 2, as represented by equation (1). Only variables internal to the organization are included in the model, and optimal values are computed as functions of other internal variables. In order to bring the findings within the bounds of acceptability, it is necessary to specify the variables which truly cause long-run structural change and bring these variables into the model. The most important of these variables lie in the organization's environment.

In the past, there have been many organization studies concerned exclusively with relationships among internal structural variables, such as size, number of levels and administrative ratio. So long as simple correlation and regression techniques were used to describe the relationships, it was possible to exclude the environment without absurd implications. But the methodological advancement toward the specification of structural control models, which we feel is an appropriate step, requires a concomitant advancement in theory. The dynamic model throws the spotlight directly on theoretical shortcomings. It simply is not appropriate to describe an optimal organization structure in terms of itself. The infeasible optimal configuration (Table 1) provides evidence that the true causal variables lie elsewhere. Investigators must extend the theory of organizational change to include environmental

variables that cause structural changes to occur, and operationalize these variables in order to achieve valid results with this method.

For example, continuing the assumption of linearity, the following could be substituted for (1):

$$X^*(t) = AX(t) + DE(t) + B \quad (1')$$

where

$$D = \begin{bmatrix} d_{11} & \dots & d_{1k} \\ \vdots & & \vdots \\ d_{n1} & \dots & d_{nk} \end{bmatrix}$$

$$\text{and } E(t) = \begin{bmatrix} e_1(t) \\ \vdots \\ e_k(t) \end{bmatrix}$$

In this case, we suppose that k significant environmental stimuli have been identified. Since environmental factors will typically change over time, we have indicated this by the functional notation, $E(t)$. Stability in this case implies that the organizations converge continually toward an optimal structure of the form

$$X^*(t) = (I - A)^{-1}DE(t) + (I - A)^{-1}B. \quad (7')$$

As (7') illustrates, an environment-linked model implies that the optimal long-run structure of each organization is dynamic and depends upon the development over time of its own environment. We believe this makes for a more realistic theoretical specification. Here, the proper organizational structure is partially determined by internal adjustment, as in Hummon et al.'s formulation. This aspect is represented by the $(I - A)^{-1}B$ term, as before. But now, in addition, the environment of each particular organization also plays a part in determining the "right" structural configuration. This is represented by $(I - A)^{-1}DE(t)$. Since environmental factors are a function of time and subject to change, then so is the optimal structure of each organization. In addition, since the environment of each organization is different, then so will be the optimal organizational development over time. This specification thereby eliminates the double bind for the researcher. Stability no longer means that each organi-

zation's structure evolves toward the same fixed optimal state but, instead, stability implies that structural components of individual organizations adjust toward congruence with their particular environment as well as toward internal consistency.

Despite our reservations concerning the validity of the relationships in Figures 1 and 2, we shall use those findings as an example of where an investigator might look for relevant environmental variables for finance departments and high school districts. Figure 1 suggests that environmental stimuli may be causing finance departments to add new divisions. These stimuli might be demands for new services or changes in government policy. Based on Figure 2, we might hypothesize that a major external variable for high schools is community size, or number of students, which leads to the required number of teachers (P), which in turn influences other structural variables. There are certain to be additional variables which can be brought into these models. With a properly specified system, the internal structure would be expressed as a function of both itself and environmental variables. A test of the final model's appropriateness will be its theoretical believability and the computed optimal structural trajectory.

Caveat

The technique introduced by Hummon et al. is a promising one indeed, and we urge its further use. We feel Hummon et al. have made a substantial contribution to the methodology for studying organizational development and realize that data for environmental variables were not available to them. However, we warn future users of the technique that the best results can be obtained only when their theory and data are up to the method. When the model is properly specified, each structural variable will be only partly determined by other structural variables. The environment will also play a role in determining organizational configuration. Under a properly specified model, stability will imply that organization structure follows a developmental trajectory determined by the path of environmental rather than evolving toward a fixed stationary state.

REPLY TO DAFT AND MACMILLAN

We appreciate the comments of Daft and MacMillan on our earlier paper (Hummon et al., 1975) and we shall address ourselves to some of the specification problems they raise.

They remark that we imposed the requirement of stability in order to achieve a satisfactory dynamic interpretation of our results. We disagree. Our original argument (p. 817) presented the idea of examining the eigenvalues of our coefficient matrix with a view to assessing the stability properties of the process of organizational change as we represented it. We presented the "decoupling" of our system to make clear the ideas of stability analysis. We did *not* impose the *requirement* of stability on our model. The model is interpretable under either stable or unstable conditions. Daft and MacMillan are, however, entirely correct in pointing out our lapse when we asserted that the organizations we analyzed were not evolving to a fixed optional structure. Indeed, our empirically estimated model contradicts such a statement. We erred by failing to stress the importance of the time frame required to interpret any empirical dynamic model. Daft and MacMillan argue, "It does not seem meaningful to consider short-run outcomes of the model and ignore the long-run outcomes." Again we disagree. Why not ignore long-run outcomes that have little credibility especially as they require projection over very long periods of time—in this case around five decades—when the observational period was half a decade? We remain convinced that the model can be interpreted usefully in a short-run time frame.

The most important point of their note is the specification of

$$\dot{X}(t) = AX(t) + DE(t) \quad (1)$$

as a more appropriate model¹ of organizational change where, in their notation, $X(t)$ denotes a set of time-varying endogenous variables characterizing organizations and $E(t)$ denotes a set of time-varying exogenous variables characterizing the environments of organizations. The matrix D describes the organization-environment interface and the matrix A describes the processes internal to an organization.

Daft and MacMillan suggest a seemingly straightforward and appropriate modification of the model we proposed earlier. However, mathematical models are most useful when a balance between theory, models and data is maintained (see Doreian and Hummon, 1976: 23-8; Leik and Meeker, 1975: 9-14). A breakdown in any one of these compromises the rest, and constructive developments in one have implications for the other two. Daft and MacMillan credit us with a substantial contribution to the modeling² of organizational change and go on to observe that such an advance requires a concomitant advance in theory. This should come as no surprise, but it also behooves us to consider some of the implications of using a model like that of equation (1). Our response to this comes in two parts and deals with two broad issues: (1) what kinds of theoretical advances are being contemplated and (2) what sort of data analytical implications does such a model have?

First, we would like to discuss the model in the context of the set of theoretical ideas that are currently receiving considerable attention in organizational research literature. Specifically, we describe how the model can be used to represent and evaluate contingency theories of organizational structure. While there appears to be little consensus on a precise statement of contingency theory, the following ideas and concepts run through the literature.

Formal organizations are open systems that interact with their environments. These interactions cause organizations to change their structures so that they are better able to cope with environmental influences and demands. Furthermore, according to this approach, the better an organization's structure is adapted to its environment, the more effective is the organization's performance.

Now consider the model of equation (1). The

¹ The matrix $E(t)$ contains a column of ones and Daft and MacMillan's term, B , has been absorbed into D .

² They talk of methodology but we see our contribution, such as it is, in terms of model formulation.

matrix A describes the process of structural change (adaptation), and the matrix D describes the process of environmental influences on specific elements of an organization's structure. Thus, it would appear that the model can describe the open system—structural adaptation part of contingency theory. The patterns of the elements of the matrices A and D provide an interpretable empirical map of these processes. Moreover, the time constraints of the system provide information on how rapidly adaptation occurs, and these values can be compared to the rates of environmental change to assess whether organizational change is phased to environmental change.

Suppose a researcher wanted to use the model to evaluate contingency theory. Suppose further that he or she had a data set consisting of the following types of variables: measures of organizational structure such as differentiation, hierarchy, numbers of productive employees and number of supervisors; measures of environmental variables such as complexity and the volume of workload demanded of an organization; and a measure of organizational performance. Such a data set also would have to incorporate time, either as a two or more wave panel design or as a complete time series on two or more organizations.

The model could be estimated for two subsets of organizations, one subset consisting of organizations with "high" performance measurements and the other organizations with "low" performance measures. According to contingency theory, high performance organizations ought to have structures which exhibit a more rational adaptation to environmental influences than low performance organizations. We would hypothesize that organizations operating in environments where change in complexity is relatively more important than change in workload would exhibit an adaptation pattern similar to the state finance department of the Hummon et al. analysis, for which change in structural variables is driven by adaptation in differentiation and hierarchy. Conversely, we would hypothesize that organizations operating in environments where change in workload is relatively more important than change in complexity would exhibit an adaptation pattern similar to the schools studied by Daft and MacMillan for which structural change is driven by changes in the number of production employees and, to a lesser extent, the number of supervisors. (Thus, contingency theory can accommodate multiple patterns of structural change if these patterns can be linked to differences in organizational environments.) It must be stressed that these are hypotheses that could be eval-

uated through the use of the model; the empirical patterns for finance departments and schools are used only to illustrate what we mean by patterns of rational adaptation.

Finally, if the high performance organizations exhibit these kinds of rational adaptation patterns and low performance organizations exhibit these patterns to a lesser degree, contingency theory would be supported.

We believe this extended example illustrates the theoretical power and usefulness of the model in the form proposed by Daft and MacMillan.

Having argued that there is great theoretical potential in the model suggested by Daft and MacMillan, we now consider data and estimation issues. Three data formats need to be considered: (1) when a time series of observations is available for a single organization, (2) when time series are available for a set of organizations (without any necessary correspondence of the time points when data were collected) and (3) the panel study format. The solution form to equation (1) can be written as

$$X(t) = e^{At} X(0) + \int_0^t e^{A(t-\tau)} DE(\tau) d\tau \quad (2)$$

and our subsequent discussion hinges about this equation. The case where a single time series is available has already been dealt with (Doreian and Hummon, 1976: chs. 4-5). The solution form was recast, after a change of variable for time to acknowledge the regular discrete observational form of the data, as

$$X(n+1, T) = e^{AT} X(n, T) + A^{-1}[e^{AT} - I] DE(n, T) \quad (3)$$

where T is the time interval between observations. From empirical estimates of e^A and $A^{-1}[e^A - I]D$, it is possible to recover estimates of A and D. Each equation in (3) takes the form of an endogenous variable being predicted from lagged endogenous and exogenous variables. As the data are time-series data, an autoregressive disturbance term is incorporated. An iterative maximum likelihood (MLE) estimation procedure was devised to estimate the matrices in (3). Any desirable properties of these estimators would be preserved under the complex transformations needed to recover estimates of A and D. We would now, in contrast to our article, emphasize an MLE approach in this context.

The second case of a set of time series can be handled in several ways. We suggest that procedures for interpolation and extrapolation can be used to create a close approximation to the panel format as discussed below. Alternatively, each organization could be treated separately as in the first case. The matrices A and D then could be treated as new variables to be analyzed. Such a strategy is suggested by the

work of Baloff (1966) on organizational start-ups, although the models he considered were of an altogether different, and less complex sort.

The case of panel studies appears to be much more difficult. Our earlier article (Hummon et al., 1975) had only two waves without measurement of exogenous inputs. To handle measurements on exogenous variables, we would have taken the solution form of equation (2), specified a specific functional form, e.g., exponential in t for $E(t)$. We then would have used the data on the exogenous variables for each organization to parameterize that form and have integrated the integral in equation (2). The specific solution form would specify an equation to be estimated which would involve endogenous and exogenous variables together with some constraints generated by our treatment of the exogenous variables. An iterative MLE approach could then be used to estimate the system of equations. Finally, we would work back to the specified model, undoing the transformations used to generate the estimation form.

Suppose we had more than two waves of data in a panel study format. The data then can be regarded as a time series of cross-sections of observations on organizations. This can be treated in terms of the pooling of cross-section and time-series data. Here, the pioneering work of Nerlove (1971) becomes relevant, but not, it seems, immediately so. The evidence garnered by Nerlove and others deals with two broad situations: (1) where the number of units (organizations) is reasonably large and the time series of cross-sections is reasonably long and (2) where the number of organizations is small and the time series is short. For the former, analytical results can be appealed to and, for the latter, we have only the results of Monte Carlo simulations. These are suggestive, but far from conclusive. Most likely, sociological

applications will be located in the second, and more messy category. This leaves unresolved many statistical issues, but a start has been made by Hannan and Young (1977) to deal with them.

This exchange of comments between Daft and MacMillan and ourselves illustrates one of the important features of model building; progress in formal modeling requires, and normally generates the simultaneous development of theoretical sophistication, the broadening of empirical scope and the extension of estimation procedures.

ITEMS (Continued)

Masters Degree Program for Executives, Graduate School of Business, Columbia University. He is studying coping patterns and adjustment to career/life experience for mid-career managers and professionals.

■ **NICHOLAS C. MULLINS** (The Group Structure of Cocitation Clusters) is Associate Professor of Sociology at Indiana University. He is working on structural, institutional and intellectual aspects of scientific specialties (with Lowell L. Hargens). He also is studying the rhetorical resources of natural-science writing and speaking and the theoretical implications of changing sociological methods. He has written *Power, Social Structure and Advice in American Science*. **LOWELL L. HARGENS** is Associate Professor of Sociology at Indiana University. He is collaborating with Mullins on the comparative study of specialty groups in science. He also is doing comparative research on scientific disciplines which extends the work reported in his Rose Series monograph, *Patterns of Scientific Research*. **PAMELA K. HECHT** is Assistant Professor of Sociology at the University of South Carolina. Her current research is on the social structural networks of urban areas and communities. **EDWARD L. KICK** is a graduate student in the Department of Sociology, Indiana University. His current research includes an examination of the structure of cooperation and conflict in the international system (with David Snyder) and a study of reconstructions of reality among retired sociologists (with Frank R. Westie).

■ **ALAN C. KERCKHOFF** (Realism of Educational Ambitions) is Professor of Sociology, Duke University. He is investigating the effects of early career contingencies (marriage, parenthood, military service) on educational and occupational attainment.

■ **TRAVIS HIRSCHI** (Intelligence and Delinquency) is Professor in the School of Criminal Justice, State University of New York, Albany. He is currently engaged (with Michael Hindelang and Joseph Weis) in research on the measurement of crime and delinquency, with special attention to the discrepancies between self-report and official measures. **MICHAEL J. HINDELANG** is Professor in the School of Criminal Justice, State University of New York, Albany. Since 1973, he has been involved with analyses of the results of the LEAA/Census victimization of persons, households and businesses. He is collaborating with Hirschi and Weis on the N.I.M.H. study of self-reported delinquency techniques. He is the author of *Criminal Victimization in Eight American Cities* (Ballinger, 1976) and co-editor of *Sourcebook of Criminal Justice Statistics—1975* (U.S. Government Printing Office, 1976).

■ **JOHN HAGAN** (Rediscovering Delinquency) is Associate Professor of Sociology at the University of Toronto and is presently on leave at Indiana University. His current research includes "The Urban Youth Project: A Study of Life Space and Juvenile Delinquency," "A Study of Victim Involvement in the Criminal Justice System," and (with Jeffrey Leon) a comparative analysis of strategies of crime

control in Canada and the United States, with particular focus on issues of right to counsel. His most recent book is *The Disreputable Pleasures* (McGraw-Hill Ryerson, 1977). **JEFFREY LEON** is Lecturer, Centre of Criminology, University of Toronto, where he is completing his LL.B. He is presently involved in research on legal representation for children, legal and epidemiological issues in drug use and (with coauthor John Hagan) the comparative study described above.

■ **JAMES R. KLUEGEL** (Subjective Class Identification) is Assistant Professor of Sociology at the University of California, Riverside. He is currently pursuing research on recruitment to authority positions in organizations as an aspect of socioeconomic achievement. He has a continuing interest in the nature and consequences of stratification ideology, including subjective evaluations of the meaning of social class. **ROYCE SINGLETON, JR.** is Assistant Professor of Sociology at the College of the Holy Cross. His work on the present paper stems from interest in subjective dimensions of social class and in general measurement issues in sociology. He also is doing research on the group polarization of judgments and attitudes. **CHARLES E. STARNES** is Assistant Professor of Sociology, Oregon State University. He is currently engaged in a study of methods and uses of Social Impact Assessments in natural resource decisions and a study of sociological implications of alternative measures of inequality used by economists. He is the coauthor, with Jonathan H. Turner, of *Inequality: Privilege and Poverty in America* (Goodyear, 1976).

■ **RICHARD RUBINSON** (Democracy and Social Inequality) is Assistant Professor of Sociology at Johns Hopkins University. His present research includes studies in the development of the modern world-system, with special focus on the forms of political organization, and a longitudinal study of the conditions of educational expansion in the United States from 1870 to 1970. **DAN QUINLAN** is a candidate for the Ph. D. at Johns Hopkins University. His research interests include the effects of world economic position on income inequality and political development and a study of the antecedents of birth experience with special emphasis on prepartum training.

■ **CARLTON A. HORNUUG** (Social Status, Inconsistency and Stress) is Assistant Professor of Sociology at the University of Maryland, College Park. His research interests lie in social stratification, particularly theories of social consistency, and in medical sociology. He is currently completing a three-year study of continuing medical education activity of office-based primary care physicians which is supported by the Public Health Service, National Library of Medicine. He is coauthor, with Mark Abrahamson and Ephraim H. Mizruchi, of *Stratification and Mobility* (Macmillan, 1976).

■ **GUILLERMINA JASSO** (Distributive Justice and Earned Income) is Assistant Professor of Sociology at Barnard College and the Graduate Faculties of Columbia University. She is working on

ITEMS (Continued)

a mathematical theory of individual and social behavior. PETER H. ROSSI is Professor of Sociology and Director, Social and Demographic Research Institute, University of Massachusetts, Amherst. He is presently studying the long-range impact of natural disasters and making an analysis of results of field

experiments on use of transitional monetary aid payments to released prisoners to reduce recidivism. He is coauthor, with Katharine Lyall, of *Reforming Public Welfare* (Russell Sage Foundation, 1976) and, with Richard A. Berk, of *Prison Reform and State Elites* (Ballinger, 1977).

ERRATUM

An incorrect reliability coefficient for Armer's modernity scale was used in the structural equation analysis in Michael Armer and Allan Schnaiberg's reply to the comment by Cohen and Till (ASR April, 1972, pp. 378-382). Eliminating one item that had a negative item-to-scale correlation in the Armer scale results in an alpha of .596, standard deviation of 3.462, and modified correlations with other scales: Smith-Inkeles' (.569), Kahl (.612), SES (.413), and anomia (.530). Reanalysis using the corrected reliability coefficient modifies path coefficients to Armer's scale from modernity (.49), SES (.28), anomia (-.64), and residual disturbance (.02). These estimates lead to a substantial revision of the percentage contribution to scale variance attributable to invalidity factors (74.5%), "modernity" (23.5%), and disturbance factors (2.0%). The corrected results parallel those for Smith-Inkeles' and Kahl's scales, which remain virtually unchanged, and strengthen rather than weaken the conclusion regarding the invalidity of modernity scales.

By Hans Toch
School of Criminal Justice,
State University of New York
at Albany.

(For further information on the
Hadley Cantril Award write to
P.O. Box 9714, Washington, DC 20016).

Winner of the Hadley Cantril Memorial Award for 1976

"*Men in Crisis*"—a compelling and sensitive exploration of the differing crises of men (and women) confronting the shared stresses of prison life; a demonstration that objectivity is compatible with compassion and that systematic inquiry can honor the uniqueness of the individual." —from the Award Citation

The book examines a wide spectrum of feelings and thoughts of men who break down under the harshness and deprivation of life in a penal institution. It concludes with an extended discussion of strategies for intervening in the varying kinds of personal crises experienced.

Working-Class Women and Grass-Roots Politics

By Kathleen McCourt

Reports on the involvement of white, working-class women in community organizations and analyzes the role transformation and resulting conflicts some working-class women are experiencing as well as the potential for change represented by this new grass-roots populism.

256 pages \$10.00

The Case for the Welfare State

By Norman Furniss and Timothy Tilton

This innovative book argues that debate should be focused on the current problems of advanced industrial societies: bureaucratic responsiveness, citizen participation, persistent poverty. The comparative discussion of welfare provision in Britain, Sweden, and the United States is thoughtful and enlightening.

256 pages \$14.00

The Irish Diaspora in America

By Lawrence J. McCaffrey

The full story of the Irish in their own land and in America, including the implications of their loss of ethnic identity. "... an expert's book, with many aspects and a mountain of material and suggestion."

—*Times Literary Supplement*

224 pages \$8.50

Pursuing the American Dream

White Ethnics and the New Populism

By Richard J. Krickus

A brilliant overview of the experience of white ethnic groups which delineates their peculiar heritage, evaluates their contributions, and confronts their current dilemma. "... a remarkably interesting, readable, and useful book. ... deserves a wide readership."

Women, Crime and Criminology

A Feminist Critique

CAROL SMART

Trent Polytechnic, Nottingham

'In this scholarly treatise, Smart not only presents the various theories of female criminality, but discusses studies of prostitution, rape, the treatment of women as offenders and victims [and] the relationship between female criminality and mental illness . . . A good addition to any serious criminology collection.'

— Suzanne Plessinger, *Library Journal*

Images of Law

**ZENON BANKOWSKI and
GEOFF MUNGHAM**

*University of Edinburgh; and University
College, Cardiff*

This introduction to the relationships between law and a capitalist political economy contends that law as it is practised and taught today means oppression and desolation. The authors use their own valuable experience in law and social science to demonstrate that the attempt to give the law a 'human face' does not differ from the traditional 'rich man's law'. *paper \$6.50*

Law and Society

ADAM PODGORECKI

*Professor of Sociology, University of
Warsaw*

'A valuable addition to the literature about the acceptance, rejection, or modification of law by various social elements . . . especially for legal systems only little known to most American scholars.'

— Isidore Silver, *Library Journal*

Knowledge and Social Imagery

DAVID BLOOR

*Science Studies Unit, University of
Edinburgh*

Is the sociology of knowledge applicable to objective science? This book argues that it is. In an untechnical way it discusses the philosophical problems raised by this contention and probes into the sources of resistance to this approach by a sociological analysis of our conception of knowledge. *paper \$7.50*

Legitimacy and the Politics of the Knowable

ROGER HOLMES

London School of Economics

Foreword by Professor Donald G. MacRae

Roger Holmes's work in social and industrial psychology is widely respected. The theme of this first collection of his essays is the relationship of the individual with the formal, value-laden group on the one hand and the scientifically known and the philosophically asserted on the other. The essays are excellent . . . an excellent source for in-depth discussions.' — *Choice*

paper \$11.50

The Organization and Impact of Social Research

*Six Original Case Studies in Education
and Behavioural Science*

Edited by MARTEN SHIPMAN

*Director of Research and Statistics,
Inner London Education Authority*

'The authors of six widely quoted pieces of educational research describe in detail the origins, planning and implementation of their studies. These insightful and candid accounts go behind the public mask of research as presented in books and journal articles . . . should be compulsory reading for all about to embark upon the treacherous trail.' — Peter Barnes, *New Society*

paper \$8.25

MATTERS OF LIFE AND DEATH.

CASE STUDIES IN MEDICAL ETHICS

Robert M. Veatch

In this important and topical new work, Robert Veatch explores the ethical implications arising from modern technological advances in biology and medicine.

Using more than 100 case studies as examples, Veatch identifies ethical issues in situations ranging from the everyday to the exotic.

He examines the ways decisions concerning the ethical aspects of medical care are made, as well as their possible consequences and alternatives.

The issues discussed include abortion, sterilization, hemodialysis, genetic counseling, experimentation, and dying.

Anyone affected by the burgeoning power of medical intervention will gain new insight from this book.

Statistical Methods for Social Scientists

By ERIC A. HANUSHEK and JOHN E. JACKSON

A Volume in the **QUANTITATIVE STUDIES**
IN SOCIAL RELATIONS Series

Covering contemporary methods of quantitative analysis as used in sociology, economics, and political science, this text shows how to apply statistical methods in estimating and testing social science models. After an introduction to analytical modeling, the book develops simple regression methods—for both single equation and multiequation models—and discusses their application and the complications that might arise. It features coverage of the increasingly important topics of qualitative dependent variables, errors of measurement, and unobserved variables. It also relates the techniques covered to more specialized areas such as path analysis and factor analysis.

1977, 392 pp., \$19.00/£13.50 ISBN: 0-12-324350-5

OPENING ENCOUNTERS *

DEBORAH SCHIFFRIN

University of Pennsylvania

American Sociological Review 1977, Vol. 42 (October):679-691

This paper examines the social organization of opening encounters. A base form of opening sequences is suggested, and adaptations of this base form are used to illustrate how the ritual and formal structure of openings interact with variable social and personal circumstances. Some general relationships between recognition, ritual, interaction and social order are suggested; and the implications of these relationships for understanding the structure of ongoing conversation and their relation to social organization are considered.

Everyday social activities, such as conversations, meetings and parties, impose specific demands on their participants. For example, individuals are required not only to be physically present for an activity, but to express a psychical or emotional presence as well, such that they may be said to be "alive" to a situation and "properly involved" with their partners in the activity (Goffman, 1963a). At the same time, each participant in an activity is required to show identification, or *cognitive recognition*, of the other as a viable partner in that activity. Such identification involves not only identifying an individual as being a certain person, with a known identity, but more generally, it involves the sorting out and categorizing of known from unknown individuals, and those acceptable for interaction from those unacceptable.

Although the sorting-out procedure is cognitive in nature, the production and provision of the cues which promote such categorization are socially organized both on a societal and individual level; and societies, as well as individuals, differentially produce, interpret and use identificatory cues (see, for example, Lofland, 1973). Despite such variation, the function of those cues and the identifications which de-

pend on them is constant in at least one respect: they separate acquaintances from strangers, one personal acquaintance from another, one sex from another, one ethnic group from another, and so on. In short, they symbolize that such differences are socially meaningful. Given this function, it is not surprising that individuals display both their own identities and their cognitive recognition of others' identities and, further, that the production and interpretation of such *identification displays* is also socially organized.

An identification display alone, however, is neither socially nor ritually sufficient as evidence of personal identifications, at least if such identifications are to be followed by face-to-face interaction. Displays preceding such interactions between acquainted individuals need to signify not only cognitive recognition, but also acknowledgment of the heightened expectations and obligations inherent in the increase in mutual access, which an upcoming interaction contains. *Access displays*, then, signal not cognitive recognition but *social recognition* or "the process of openly welcoming or at least accepting the initiation of an engagement" (Goffman, 1963:113), thus showing that such expectations and obligations are being met.

Although much ongoing interaction is concerned with recognition displays, such displays are intensified and most ritualized in the opening and closing portions of encounters: openings use recognition displays

* I would like to thank Erving Goffman, William Labov, Diane Levy Miller, Dean MacCannell, Louis Scavo and two anonymous ASR readers for helpful criticisms of earlier drafts of this paper.

to demonstrate that time apart has not threatened a relationship in the past, and closings, to demonstrate hope that time apart will not threaten it in the future. Because human ritual is formal and technically efficient (Huxley, 1966) as well as symbolically meaningful (Goffman, 1967), it provides a means by which individuals can readily and efficiently express whatever recognition is demanded, even in one of the briefest of rituals, passing greetings; i.e., those which terminate the minimal increase in accessibility only seconds after its initiation, yet still leave open the possibility for future contact (Goffman, 1971:75-6), and opening greetings, which not only leave open a possibility for future contact but immediately actualize it.

In this paper, I will argue that cognitive recognition and social recognition, and their display in identification and access displays, are important in both the maintenance of social order and in the organization of social interaction. In order to do this, I will suggest a framework which treats cognitive recognition, identification displays and access displays as phases within an *opening sequence*. The main part of this paper will use this framework as a base from which to show transformations of the recognition structure of opening sequences in response to variable social and individual circumstance. Despite such circumstance, such transformations or *adaptations* maintain social order and the coherence of interaction. In conclusion, I will suggest some relationships between opening encounters, recognition, interaction, and social order.

Opening Sequences

Cognitive recognition. Before social interaction occurs, individuals cognitively recognize each other; that is, they "place" or identify another by "linking the sight of him with a framework of information concerning him" (Goffman, 1963: 112). For example, an individual is *categorically recognized* as a member of an ethnic group, a race, a social class, and so on, and such a sorting-out process helps to differentiate potential from non-potential interactions and to organize and qualify those which occur. Interactions based on categorical

identification are different from interactions with acquaintances, which are based on personal identifications. Before these can occur, individuals must *biographically recognize* one another on the basis of personal information. This process differentiates potential personal interactions from non-potential ones and qualifies those which occur; but beyond doing this by just sorting out one category of individuals from another (known from unknown), it also specifies who those personally-known individuals are. Only the latter type of interaction and identification will be considered here.

Cognitive recognition display. Cognitive recognition is not always displayed, but as Goffman (1963:113) notes, "it is difficult to engage in without expressing that one is doing so." Such *identification displays*, then, are the first ritually-required display in opening encounters, especially if it is known by the individual that he has been so identified. For example, upon identification of a personal acquaintance, one's eyes may light up, one may smile, walk briskly toward the other, call the other's name, "yoo-hoo," mutter to oneself, and so on.

Despite being ritually required under certain conditions, however, the function of identification displays is more technical than ritual: they externalize a correspondence between the appearance of a specific individual and an identificatory framework based on such an appearance which allows for personal identification. In other words, because identification displays are an open assertion that an individual has "been seen" in this cognitively referential way, they express the fulfillment of a technical requirement for personal interaction—that individuals personally know one another. Note, however, that just as human interaction requires more than the fulfillment of purely technical or formal conditions such as identification, opening sequences do so too. Therefore, even when identification displays are overlaid with imputations of ritual meaning, as when delight in identification of a friend is displayed by a high-pitched squeal, they are *not* greetings and they are not complete as opening sequences.

Social recognition display. Greetings occur after identification displays. Because they show that further access is ritually

and socially permissible, greetings are *access displays* and, as noted above, they signify not cognitive recognition, but social recognition.¹ Access displays do this by symbolically conveying a social identity and membership in a relationship: they make participants "present" to one another in a special way" (Callan, 1970: 115) and place them within a social context as specific social entities (Firth, 1972). Thus, the main function of greetings—to increase ritual accessibility—is ritual, rather than technical.

The sequence. The obligatory sequence of cognitive recognition, identification display and access display exhaust the ritual interchange between two acquainted individuals which accompanies an initial increase in their potential for mutual accessibility. It is this interchange which I call an opening sequence as represented in *Sequence 1*:

<i>Sequence 1:</i>	<i>A:</i>	A1	A2	A3
<i>Base form</i>	<i>B:</i>	B1	B2	B3

Such a representation can be read as a formal depiction of either the structure of opening sequences or production rules for participants representing possibilities for action within normative limits. Individuals are *A* or *B* and the three stages are represented with corresponding numbers. Reading across denotes sequential ordering of moves and, reading down, simultaneous occurrence.²

¹ When the term "social recognition" is used in a broader sense, e.g., as knowledge of specific social and cultural expectations and obligations, there is a cognitive side to social recognition displays to match the cognitive side of identification displays. Although such knowledge is certainly required for social interaction, in opening encounters the fulfillment of such norms (not just the knowledge of them) is displayed when one individual welcomes the initiation of an engagement with another and socially recognizes him in this narrower sense.

² *Sequence 1* suggests (and, I would argue, correctly) that in a base form of openings, *A* and *B* begin simultaneously and, therefore, it is the potential increase in accessibility which generates openings between acquainted individuals, not the first individual's greeting which generates the second's. This is not to deny that a second greeting is conditionally relevant on a first, but this dependency should not be allowed to obscure the ritual motivation behind both greetings. Thus, if

Adaptations

Adaptations of the base form of openings in *Sequence 1* illustrate how the ritual and formal structure of opening sequences interact with variable social and personal circumstance. The data used to illustrate these adaptations are typical of those in a set of 75 openings: of which I participated in 35 and observed 30, with the rest reported to me.³ Openings aren't limited to any one occasion or locale, so I recorded them whenever and wherever they occurred, and as soon as opportunity would allow. Because I wanted to observe natural behavior, the sequences were not generated intentionally for data or manipulated for certain effects. In recording, I noted as much as I could remember without limiting myself to any particular feature of the interchange. Obviously, this method of observation is less rigorous than some others, e.g., video tape; but the behavior that I was interested in was most amenable to this method. Most of my data are limited to white members of the American middle class; social class and racial differences would certainly produce stylistic differences.

Although all of the opening sequences discussed here were represented in my data, they do not exhaust the total range of opening possibilities. I would argue, though, that the existence of sequences, which are merely further modifications of

it were the case that a first greeting generated a second, we would still have to figure out why that first greeting occurred; and if we were to suggest that first greetings had different causes than second greetings, we would have to explain why two functionally equivalent and structurally interchangeable moves had different causes.

³ Despite the relatively small data base in which this framework was grounded, its validity can be examined on several levels: (1) empirical—how much of the behavior in openings can be described, how accurately, how parsimoniously, what is the range of openings which can be described both ritually and formally; (2) structural—is there a logical relationship between the stages within the scheme, is it internally consistent; (3) theoretical—does this scheme provide any new insights about interaction and social order which build on what we already know, does it suggest any new generalizations or any revisions of previous models.

the base form of openings, is more a strength than a weakness, especially with a heuristic scheme such as this. Note, also, that the observations which I used to formulate both the base and adaptive forms were assembled *before* the recognition framework was developed. I continued to observe openings without adding them to this data base (although I would have re-evaluated the framework if I had found a sequence that didn't fit) primarily because I wanted the base form and the adaptations to be grounded in the observations that I had collected before analyzing openings in the categories of the recognition framework, to be sure that I didn't consequently observe and record *only* what could be seen in those terms. However, in both the original set of openings and in those that I've continued to observe without recording, I have found none that couldn't be analyzed in this framework.

Recyclings. Misidentifications occur when an individual is linked with a framework of information which does not accurately relate to him. When a misidentification is discovered, the individual substitutes the relevance of one identification for another with a *double-take*; but if the misidentification has already continued into a display, the double-take has to be accompanied by a withdrawal of the display in a *take-back*. Both of these recyclings are illustrated in *Encounter 1*:

- (1) DS is standing at a bus stop.
Four men in a car stop at the light and look at DS.
DS looks at the car, then looks away.
- DT—DS looks at the car again, especially at a man in the back.
DS raises her eyebrows, peers into the car.
DS Hi-i-i (softly, questioningly); waves.
Man waves (exaggerated) and leans forward, laughing.
Other men in the car also lean forward and laugh.
- TB—DS Oh (to self) whoops.
— H-h-eh, sorry (softly); grabs hand back.
— Shit (to self).

Double-takes, then, rearrange opening sequences because they recycle back to a second round of identification, with only one leading to the opening displays (or civil inattention) appropriate to the identification. Take-backs recycle back to a second

round of identification and/or access displays (or lack thereof).

Encounter 1 illustrates a misidentification in which DS misidentifies a stranger as an acquaintance: she thought that she knew the man in the back of the car. The double-take and take-back resulting from that misidentification are represented in *Sequence 2*.

*Sequence 2:*⁴

Double-take/take-back

I	II
A: A1 ₁ (A2 (A)) ₁ Φ [A1 ₁ (A2 (A3)) ₁]	
B: — — —	— — —

With the opposite sort of misidentifications, that of acquaintances as strangers, openings also recycle; and, in either case, the recycling involves the resorting of an individual into a more appropriate category. *Encounter 2* illustrates this type of misidentification.

- (2) EM is sitting in a downtown office building;
EM is visible to the street; he is staring at the street.
DS walks by the building; she recognizes EM.
DS smiles.
EM continues to stare into the street, without focusing on DS.
TB—DS (to self) He doesn't remember who I am.
—DS's smile continues until she is past the building, but it is no longer directed at EM.

The recycling in *Encounter 2* is also represented by *Sequence 2*.

Note, next, that there is a dependency between double-takes and take-backs. In

⁴ Explanation of symbols:

- I, II, III... recycling of sequences
() optional
()₁ if option was taken in first cycle, has to be taken in second; with 1', if option *not* taken in first, has to be taken in second
[] obligatory application of operation preceding brackets, to phases within brackets
 Φ delete
— no behavior relevant to opening sequences
{ } obligatory selection of one within curly brackets; subscripts indicate that whichever was chosen, the one on the same line in the next set of curly brackets should be chosen

Encounter 2, for example, if *EM* had recognized *DS* in time, her take-back would have become unnecessary and the encounter would have continued into hellos. This possibility, that a double-take by the already-identified individual can alleviate the need for a take-back by the identifier, is represented in *Sequence 3*:

Sequence 3:
Double-take

I			II		
A:	A1	A2 (A3)_1	—	A2 (A3)_1	
B:	—	—	B1	B2	B3

This dependency also is illustrated when an individual is forced to begin recycling with a take-back because the other individual has seemed not to recognize him, but then has to undo that take-back with the other's eventual recognition. Thus, what occurs is a negation of a negated display, or a redone display, as in *Encounter 3*:

- (3) *SW* is walking on a downtown street.
DS is walking towards *SW*.
DS recognizes *SW* and smiles.
SW stares past *DS*.
 DT—*SW* turns around quickly.
 TB—*DS* has already compressed her lips.
SW Hi, Debby.
 TB/TB—*DS* Hi! I didn't think you recognized me . . . warm out, isn't it?

That an individual's late identification and double-take can alleviate the need for the other's already begun take-back and create the need for a redoing of the display as in *Encounter 3*, is represented in *Sequence 4*:

Sequence 4:

Late double-take/take-back

I			II		
A:	A1	A2 (A3)_1	$\Phi[\Phi\text{—}\text{A2 (A3)}_1]$		
B:	—	—	B1	B2	B3

Note that the dependency between double-takes and take-backs is due to their timing: a prompt double-take can prevent the need for a take-back. Because of the nature of this dependency, certain ritual complications develop when the misidentifier has *not* done a double-take at all and, therefore, has not been able to take back his displays in time. This was the situation of *Encounter 1*, for example. *Encounter 4* also illustrates these complications:

- (4) *MS* is walking on a beach; walking towards her is a woman and an elderly man.
MS walks over to the woman.
MS Oh, Judy! Hello!
J (looks confused; looks at the man with her)
 DT/TB—*MS* Oh! You're not Judy! But you look just like her! And you're pregnant too!
J Everyone confuses us. She's my cousin!
 (to *MS* and man with her, while laughing and shaking her head).
MS Oh! Isn't that funny! Well, have a nice walk!

Two ritual binds requiring remedy are created in situations like these. First is an appropriateness bind. A ritual should not be initiated with a ritually unavailable person, and any attempts to complete one that has been initiated, only prolong what is inappropriate. The behavior of *MS* remedies this bind by closing the encounter in a manner similar to the way she might have closed it with the real *J*: her talk not only fills the empty interactional slots, it signifies that although *J* is the sort of person with whom a similar encounter would not have been offensive, *MS* is not the sort of person to exploit the inappropriate availability. Thus, identities are preserved, civil inattention is resumed, and a potential ritual offense is avoided.

Second, a completion bind is produced: an inappropriately initiated ritual has to be completed and closed, but cannot be completed efficiently when neither individual was ritually accessible in the first place. One remedy for this bind is to fill the empty slots with talk about the experience itself: since both individuals have participated in the inappropriate initiation of a ritual, talk about it creates a momentary bond which substitutes for the bond that was supposed to be signified by ritual. Such meta-comments may be spoken of as reflexive frame breaks (Goffman, 1974:502). Thus *MS* shares with *J* the only experience which is theirs to share, the misidentification.

Similar complications and binds develop with misidentifications of one personal acquaintance as another. Here, even more confusion results because although remedial work is required, so too are recognition displays and, although some have been offered, they have been misdirected. *Se-*

quence 5 represents this reordering, in which entire new sets of both identification and access displays have to be worked up by the misidentifier.

Sequence 5:

Misdirected double-take/take-back

A:	A1	I			Φ	[A1	II		
		\downarrow (A2	(A3)) \downarrow				\downarrow (A2	(A3)) \downarrow	
B:	B1				—	—			
		{B2	B3}						
		\downarrow —	— \downarrow						
		III							
		A1'	A2'	A3'					
		—	{—	—}					
			\downarrow B2	B3 \downarrow					

Thus, what occurs for *A* is a rerun of the entire sequence and, for *B*, a replay of his displays. It is not surprising to find that if a misdirected display of this type is never actually received by its misidentified object, then neither individual actually is forced into complicating ritual binds. Furthermore, when the real object of the display is present along with the misidentified object, the experience is even less anomic for the displayer, whose display can be easily redirected and his experience re-anchored. For example, *Encounter 5*:

- (5) *MM* enters kitchen, where several people are seated at a round table. *RS*'s back is facing her.
MM goes to *RS* from behind.
 DT/TB—*MM* halts abruptly and laughs.
MM goes over to *MS*, who is seated on the other side of the table.
MM Oh! y'know I thought that was you, Michael—
RS (laughing) from the back—
MM —an' I was gonna go, how y'doin'! (slaps *MS* on the back)
 Everyone laughs, and a general chorus of Ohhh!
MS Thanks, hon! Oh, she's a pleasure, isn't she!

In (5), *MM* can maintain the relevance of her initial identification and can anchor her display to its appropriate object. In short, *MM* is not confronted with an appropriateness bind. *MM* is momentarily faced with a completion bind, however, and she therefore couches her display to *MS* as a reflexive frame break: she reports on her misidentification and includes her greeting as the mistake that would have occurred had the misidentification not been remedied in

time. In terms of ritual organization, *MM*'s break invites *RS* to share in her experience and it signifies that even though a display had been withdrawn from him, it was not withdrawn because of his undesirability.

In sum, misidentifications require re-categorization of personal and social identities and the realignment of identifications and displays—biographical identification with identification and access displays, and categorical identification with civil inattention. Thus, they also require that the potential for an extended encounter after the opening, e.g., a conversation, be readjusted according to the appropriate identification. Recyclings, such as the double-takes and take-backs discussed here, adapt the structure of opening sequences to accomplish these tasks and, in so doing, they organize the web of association between acquainted and unacquainted individuals and maintain the social differences between personally and categorically identified others.

Alterations. Encounters can compete with each other for an individual's attention; and when competing encounters offer alternative sources of involvement, the encounter which wins out can nevertheless be affected, as can the one which loses. For example, when ongoing involvements prevent communication channels from being opened, and make a full ritual orientation unfeasible, opening sequences can be altered to fit the circumstance.

One alteration is for an identification and access display to be squeezed together in a *compression*, to signal that although individuals are neither technically nor ritually available for talk, it is not because they are ritually undesirable. *Sequence 6* shows compressions:

Sequence 6:

Compression

A:	A1	A2
		A3
B:	B1	B2
		B3

Passing greetings are sometimes compressions, and the brief display which occurs combines the features of identification and access displays, such that hats are doffed (MacCannell, 1973), hands waved or shaken (Schiffrin, 1974), heads nodded

or hellos grunted—all typical access displays—at the same time that one's personal identification of the other is displayed. Although found together empirically, the function of the displays remains distinct, so much so that if an individual passes an acquaintance and appears to have identified him without the accompanying social recognition, the acquaintance may feel insulted. Thus, great precautions are taken so as to ensure the other's appreciation of the difficult conditions under which deference was paid, and the encounter may be literally exhausted by compressions, as in *Encounter 6*:

- (6) *A* is riding on a bus.
B is on a different bus, which has pulled next to the first.
A waves, opens mouth in smile.
B waves, throws head back, smiles, opens mouth.
A nods, smiles, waves.
B moves mouth without vocalizing.
A nods, smiles.
A and *B* both twist around in their seats as the buses separate.
B waves.
A waves.
 The buses separate.

When the contour of an ongoing involvement changes, individuals suddenly may find themselves in contact after they had already signalled that it was unavailable. Such a shift in the potential for access may accompany a transition into a different activity system, as when (for example, Post, 1940: 22–3) one smiles at a friend in church, and then greets and talks with that friend out on the church steps. Alternatively, a shift in accessibility may reside within one such system. That the unavoidable lapse in contact was not a serious representation of the individual's intent is expressed by a redoing of the identification and/or the access display at the point of renewed access.

This type of alteration, a *negative transfix*,⁵ signifies that although availability was technically impossible and ritually unfeasible, such time apart is not indicative of the

individual's evaluation of either the other's self or of the relationship. *Sequence 7* represents this alteration as a time-lapsed recycling of a portion of openings:

Sequence 7:

Negative transfix

Because negative transfixes occur in situations in which participants are not immediately accessible to one another, they often follow compressions. Thus, they are frequent during parties, meetings and classes, when individuals can only display their identification by raising an eyebrow, smiling or pointing a finger, until further access and a fuller orientation is possible. They also may occur when a full exchange of displays *has* been performed, but is prevented from its conversational follow-up until some time later. Even when an ongoing conversation is interrupted, negative transfixes can reestablish the prior structure when it is resumed, as in *Encounter 7*:

- (7) Two women enter a bus together. The bus is crowded and only single seats are available.
A Here, Dear, you sit here (points to a seat and passes it).
B (mildly grumbling) Oh no. . . .
A I'll go back here.
 Several minutes later, a seat behind *B* is vacated.
 A man *C* has just boarded the bus and is about to sit down.
A (coming up from rear of bus, to *C*) Can I sit here? I want to sit near my friend.
C grumbles and moves to another seat.
A sits in vacant seat.
 NT—*B* (turning around in seat) Hi, Dear!
 NT—*A* (touching other's outstretched hand) Hi!

In sum, opening alterations modify an underlying ritual structure to fit it to overriding social circumstances: compressions and negative transfixes make sure that the right categorization, identification display and access display is noticed despite the lack of accessibility; and they assure that the potential for contact will still remain

⁵ Suggested by Erving Goffman in a personal communication. Note that when relationships are considered in their entirety, all greetings may be seen as negative transfixes.

open, despite its not having been immediately actualized.

Strategies. Yet another adaptation of the base form of opening sequences occurs when individuals utilize the structure of the opening as a foundation for individual expression and affectation. One sort of strategy, for example, is used when contact is infrequent or unexpected and is intended to elicit extra displays of involvement and recognition in order to openly attest to the strength and endurance of the relationship. Thus, displays such as backslaps and bear hugs performed *before* the other person has had time to identify the performer are *forced double-takes*, and they may be used when formerly intimate acquaintances who see one another infrequently come into sudden contact, or when intimate acquaintances who see one another frequently suddenly come into unexpected contact.

The effectiveness of such a strategy is due not only to the base structure of opening sequences, but to the structure of double-takes as well: the recipient of the display is forced into rapidly recycling and substituting a non-personal identification by a personal identification. Formally, then, this strategy is merely a replication of an ordinary double-take, except that it is speeded up as shown in *Sequence 8*:

Sequence 8:

Forced double-take

I				II		
A:	A1	A2	A3	—	—	—
B:	—	—	—	B1		
				B2		
				B3		

The ritual effect of forced double-takes can be seen most clearly when the strategy fails to be immediately effective, as for example:

- (8) *LS* and *DS* are at a party. They are dancing, as is everyone else in the room.
GM cuts in on *DS* and begins dancing in an exaggerated fashion, holding *DS* tightly, even though the music is fast.
DS looks over her shoulder at *LS*, who is watching.
LS All right, that's enough. (pushes *GM* away slightly)
LS and *GM* stand and look at each other.
GM (loud) Whadda' y' mean, that's enough?!
LS steps up a little closer to *GM*.
 Other people stop dancing; look at *LS*

and *GM*; someone says, "Take that shit outside man, c'mon. . . ."

GM (loud, forcefully) Sca-a-v-

DT—LS (loud) Gaton!

GM hugs *LS*.

DS (to other people watching) I think they know each other.

The hug between *GM* and *LS* in (8) is a response to the extent to which *GM*'s simulated display was a disguise of his real self, and it matches it dramatically, whereas a wave, nod, smile or handshake would have been so ritually inappropriate as to suggest that *GM*'s display *had* been aggressively intended and that *GM* was not really a friend.

Thus, without a display to match the drama of the stimulation, the encounter collapses, as in *Encounter 9*:

- (9) *LS* is sitting in a car in a gas station.

FG walks up to the car window.

FG Hey man, y'got some change?

LS (half looking at *FG*) Sorry, I don't have any.

FG (starting to walk away) Oh, okay, Scavo.

DT—LS (looks up) Oh! How y'doin'?

FG (continues to walk away) Oh, okay.

LS's response is insulting because it suggests that neither *FG*'s self, nor his relationship with *LS*, are real enough to be recognized independently of the situation which frames them and, even worse, that both can be shuffled about from encounter to encounter without maintaining their integrity—precisely what the forced double-take is intended to disprove.

Ritual devastations, not unlike those unintentionally produced by the tardiness of forced double-takes, can be intentionally created as a different sort of opening strategy. For example, a misidentification of an acquaintance as a stranger can be intentionally fabricated by simply deleting the opening displays altogether. The most devastating deletion, represented in *Sequence 9*, is a *cut*, the fabrication of a misidentification in the face of the other's opening display:

Sequence 9:

Cut

I				II		
A:	Φ [A1]	—				
B:	B1	B2	1(B3) ₁	Φ [B1	B2	1(B3) ₁]

Cuts destroy the inherent reciprocity of opening encounters and, as in *Encounter 10*, leave little room for remedial work:

- (10) *DS* is seated on a bus.
NK boards and stops by the empty seat next to *DS*.
NK Debby Schiffin?
 Cut—*DS* (looks up blankly, shaking head) (slowly, doubtfully) No. . . .

DS's response to *NK*'s identification display not only refutes his identification of her but, even more strongly, it claims that she cannot identify *NK* as an acquaintance. *NK* then has to take-back his display, but, because his take-back has to be performed without the other's support, the ritual dilemmas of appropriateness and completion are left unresolved. Thus, the cut necessitates *ad hoc* constructions of alternative frames of reference: wasn't it really her? isn't she feeling well?

Because cuts are so insulting, it is not surprising that they are infrequent (e.g., Goffman, 1971:75, fn. 17). However, "carefully not seeing" an acquaintance is quite frequent, and such *snubs* are represented in *Sequence 10*:

Sequence 10:
Snub

	I		II
A:	A1	— —	—
B:	B1	1(B2 (B3))1	1(Φ [B2 (B3)])1

Along with their increased frequency, snubs are not as ritually damaging as cuts. Although both destroy the inherent reciprocity of opening sequences, snubs do not blatantly fabricate a misidentification as do cuts. Thus, rather than countering the other's display with a denial, they merely ignore it, thereby making alternative reframings of the experience more readily available: after all, that "he didn't see me" is borne out by the evidence.

Snubs are also more flexible than cuts, so that they can easily be integrated into sequences of varying form, even those whose initial identification has seemed to go smoothly, as when, for example, the second half of a negative transfix is deleted. Thus, individuals can snub one another at crowded parties by displaying their identification, but making no effort towards ac-

cess. Indeed, snubs are so flexible that they can even span boundaries between encounters, as when two politicians can snub a foreign dignitary by not providing him with a traditional reception when he arrives in their country several years after an anti-Semitic remark (see *New York Times*, 3/26/75). So not only can snubs be explained away by situational evidence, but they can be reinterpreted by the insulted as having been due to the unavailability of access, not the undesirability of selves.

A strategy even less ritually devastating and more protective of selves, but with a similar result—the avoidance of prolonged and undesired contact—is a *fast-start*. Fast-starts control the key and tempo of the opening encounter: by not waiting for the other to begin, individuals can use them to establish the temporal parameters of the opening sequence and assure that an extended encounter will not result. *Sequence 11* represents a fast-start, and *Encounter 11* illustrates one:

Sequence 11:
Fast-start

	I		II	
A:	—	—	A1	A2 A3
B:	B1			
	B2			
	B3			

- (11) *DS* (while walking by *JB*) Hi, how are you?
JB (looks up surprised) Oh, hi.

Note that formally, fast-starts are the reverse of forced double-takes (compare *Sequence 8*) and that ritually, too, they are a play on that strategy: they include the element of surprise, without the follow-through of contact.

In sum, opening strategies show how a base ritual structure can be adapted for the expression of alternative meanings. Although interactionally, opening strategies are a play on the base structure of opening encounters, they function at the same time as a vehicle for individual expression. Thus, in terms of social order, they help to sustain the fiction that the individual is a unique, creative personality, and to show that social organization is flexible enough to allow such individuality to flourish.

Opening Encounters, Interaction and Social Order

In this paper, I have suggested a framework for opening encounters. As an extension of this, I now suggest that openings be considered as encounters in and of themselves, i.e., that cognitive recognition, identification displays and access displays not only open encounters, but, by themselves, form an *opening encounter*. This view requires a slight rethinking of the traditional definition of encounters which Goffman (1961:7) has argued, i.e., that encounters occur when "people effectively agree to sustain for a time a single focus of cognitive and visual attention."

First, consider openings that are followed by encounters. Such openings precede a spate of focused activity, e.g., a conversation, party, encounters in the traditional sense, and they appear to continue without a break into that activity. The focus of attention and involvement for participants shifts, however, from the recognition displays of openings to the business at hand and, in fact, there even seem to be transition devices to smooth the flow from one frame of activity to another (Sacks, 1967). When such a shift is so regular a part of interaction, we might well speak of shifting encounters. Thus, some opening encounters, those with opening greetings, are *followed* by other encounters.

Openings with passing greetings that are not followed by other encounters suggest a different modification of the definition of encounters. Some passing greetings constitute the only focus of their participants' attention, but others occur during a more ongoing and dominant involvement. I argue, however, that such greetings are still a focused activity despite their subordination to other activities. Thus, some opening encounters *co-occur* with other encounters.

These considerations suggest, first, that the individual's capacity to split himself into several selves within one interaction might be matched by a capacity to use those selves to participate in several encounters simultaneously, or in encounters that shift from one moment to the next; and, second, that alternative sources of involvement within one encounter might rather be seen as signs

of competing encounters. With this revised and expanded description, all opening sequences can be considered as encounters.

Separating a technical aspect of interaction from a ritual aspect makes the structural parallel between opening encounters and other encounters even clearer. A technical side shows itself best in the apparatus, or machinery, by which focused interaction is organized.⁶ For example, mutual identification by participants, open communication channels, signals of mutual availability and a turn-taking mechanism are formal technical prerequisites of interaction. The technical aspect is concerned mostly with formal prerequisites such as these; but because focused activity requires *continued* dramatization of particular identities and relationships, a ritual aspect, concerned with symbolic organization and meaning, pervades both the form and content of the interaction for as long as it is sustained. Turn-taking in conversation (an aspect of form), for example, may have ritual meaning (Albert, 1972), as may the choice of locatives in place descriptions, a feature of content (Schegloff, 1972a). Conversational closings have both formal and ritual functions (Goffman, 1971; Schegloff and Sacks, 1973). In short, the technical aspect establishes the formal structure of focused interaction, and the ritual aspect overlays various parts of that structure with symbolic meaning about selves, relationships and situations.

In opening encounters, technical aspects of interaction are also overlaid with symbolism and ritual meaning, through the progressive change from a cognitive identification and its display into a ritual display of social recognition. Opening encounters, then, are a micro-structural representation of focused interaction—a kind of dramatization in miniature—which can bracket an upcoming encounter by framing precisely that structure which is about to be required: identification displays provide a technical bracket, and access displays provide a ritual frame of reference.

⁶ Compare Goffman's (1976) system requirements.

Previous analyses of greetings (Callan, 1970; Eibl-Eibesfeldt, 1972; Firth, 1972; Goffman, 1971; Goody, 1972; Youssouf et al., 1976; Irvine, 1974; Kendon and Ferber, 1973; Krivonos and Knapp, 1975; Sacks, 1967; Schegloff, 1972b) are correct in recognizing these bracketing and framing functions. However, because such analyses incorrectly identified the greeting as the only opening display, and not one display within an opening encounter,⁷ they were unable to see that openings *are* encounters; and that it is not just the greeting, but also the dependency between technical and ritual aspects of interaction which are represented in opening encounters which function to open more extended encounters.

Similarly, because previous analyses of greetings did not analyze openings as encounters, they were unable to appreciate their structural significance on a larger scale. As students of modern, urban society have noted, the transformation from a more primitive, rural folk society has resulted in a shift in emphasis—from personal relationships based on similarities to impersonal relationships based on rationality and division of labor, i.e., differences. Further, as Goffman (1967:95) has noted, the same transformation has resulted in a secular world which, however,

is not so irreligious as we might think. Many gods have been done away with, but the individual himself stubbornly remains as a deity of considerable importance. He walks with some dignity and is the recipient of many little offerings.

One way in which individuals remain deities despite the de-emphasis of personal relationships, then, is for human ritual to be so pared down that all of its work can be signified by no more than a brief passing glance and a smile, that is, a passing greeting, which, without actualizing an extended period of increased access, suggests that it would have been so, if it could, and it will, when it can.

⁷ Exceptions are Kendon and Ferber (1973), whose treatment is almost totally descriptive, and Krivonos and Knapp (1975) whose approach is experimental.

Recognition, Interaction and Social Order

Cognitive recognition, social recognition and their display are crucial not only to opening encounters, but to ongoing encounters as well; so important in fact, that a large part of social organization is concerned with making recognition and identification easier to accomplish.

Consider first, the role which recognition plays in sequences of ongoing talk or conversation. One reason for the coherence of talk is that both speaker and hearer recognize each other as valid partners in the interaction and, beyond that, both recognize, albeit implicitly, a set of culturally, situationally and topically relevant standards of conversational and interactional behavior. Thus, this sort of cognitive recognition is not unlike a "baseline" requirement for conversation, and the structure of ongoing talk includes slots in which hearers can display their recognition of the speaker as one who shares the standards, or experiences related to those standards. Through such displays as mm-hmmm's, head nods and smiles, for example, hearers show their appreciation of the other's presentation (Dittmann and Llewellyn, 1968; Jefferson 1973; 1975; Yngve, 1970).

Other than attesting to shared standards, enclosed identification displays have two more immediate interactional functions. Ritually, they express that the hearer, although not as visibly or audibly involved as the speaker, is not inattentive during the speaker's turn at talk and is sympathetic with the speaker's intentions. In this sense, these displays are similar to compressions and negative transfixes: they signify that the hearer's comparative passiveness does not indicate disdain for the speaker or for the relationship. Technically, enclosed identification displays differ from alterations in opening encounters because they respond to a situation in which technical conditions *are* being met (they maintain the technical requirement of conversation that only one person speaks at a time [Duncan, 1973; Schegloff and Sacks, 1973]), because they occur in the back channel (Duncan, 1973; Yngve, 1970) and are neither a claim for a turn nor a disruption of the speaker's turn.

Access displays also are enclosed within conversation: they occur when the speaker recognizes the auditor's right for a turn at talk and when he relinquishes his own turn (see, for example, Duncan, 1973; Sacks et al., 1974). Exchanging turns at talk, then, is a display of social recognition, i.e., "the process of openly welcoming or at least accepting the initiation of an engagement . . . [and] the according of a special role within an engagement" (Goffman, 1963:113). Thus, the according of the special roles of speaker and hearer in conversation is the same sort of dramatization: it is a display of deference for the identities which each assumes in the interaction and for the division of labor and reciprocity of access which the conversation has established.

Consider next the role of recognition and recognition displays in relation to social organization. I have argued that recognition and its displays are functional in both opening and ongoing encounters and in signifying which differences between individuals are socially meaningful. We might expect that the task of identifying, differentiating and segmenting people into easily recognizable categories (biographical or social) would be made easier somehow, for example, by multiple cues signifying the same meaning, or by cues which could be immediately and unambiguously linked with a meaning. Thus, communicative redundancy (multiple cues) and stereotyping (unambiguous meaning) can be functional on both interactional and structural levels.

Thus, not only are such communicative structures relevant on a micro-level of social organization, such as face-to-face interaction, but they are relevant on a macro-level as well, such that phenomena as seemingly diverse as a centralized articulation of a back vowel (e.g., Labov, 1972), a particular style of handshake, urban block parties in ethnic neighborhoods, or the joining together of citizens in national birthday celebrations, have more in common than might at first be suspected. All are ritual signs of identity which symbolize and help to maintain the structural differentiations of modern social organization. Perhaps an appreciation of such communicative and functional similarity can provide

an often sought-for structural link between a micro-sociological concern for face-to-face interaction and a macro-sociological concern for social structure.

MANUSCRIPTS FOR THE ASA ROSE SOCIOLOGY SERIES

Manuscripts (100 to 300 typed pages) are solicited for publication in the *ASA Arnold and Caroline Rose Monograph Series*. The Series welcomes a variety of types of sociological work—qualitative or quantitative empirical studies, and theoretical or methodological treatises. An author should submit three copies of a manuscript for consideration to the Series Editor, Professor Robin M. Williams, Jr., Department of Sociology, Cornell University, Ithaca, New York 14853.

ATTRIBUTION AND IDENTITY CONSTRUCTION: SOME COMMENTS *

JEAN M. GUIOT
Boston University

American Sociological Review 1977, Vol. 42 (October):692-704

This paper presents a tentative theoretical framework for investigating the process of identity construction. It is suggested that, at any given time, the perceiver's construction of the other's identity may be characterized by either one of two inferential perspectives. "Viewing the other qua performer" involves the attribution of role-relevant qualities on the basis of observing behavior as role performance. "Viewing the other qua person" entails the linking of observed behavior to psychological causes which have their origin in the other's personality. When the identity-construction process is envisaged in the particular case where the other is a stranger to the perceiver, an initial branching is postulated. This branching is constituted of two inferential paths (corresponding to the two inferential perspectives) potentially open to the perceiver in his construction of the other's identity. Several factors that may be invoked to account for, or to predict the nature of the perceiver's inferential activity are discussed; these include: the perceiver's needs and objectives, his expectancies concerning the likelihood of events to be encountered, his preference for certain cues in making inferences, the consequences implied by alternative categorizations and their relative value to the perceiver, the need for adjusting to situational requirements, and the kind of cues exhibited.

A number of sociologists and psychologists, in spite of important differences in their research interests, tend to concur with one another in viewing identity construction as an act which involves the placement of objects (human, physical, etc.) and events into categories (see, for example, Bruner, 1957; Berger and Luckmann, 1966).

Identity, however, is commonly conceptualized in a dichotomous manner, i.e., a distinction is made between social and personal identity in terms of type of categories used (occupational, kinship, traits, etc.) Such a distinction does, in fact, reflect more than just a differentiation among category types. As Sarbin and Allen (1968:550) point out, while "some writers imply that identity is an unfolding of personal dispositions, those with a role-theoretic orientation would declare that identity is built up from interactions with occupants of complementary statuses."

In the perspective adopted in this paper, identity refers to an integrated system of cognitions, and no qualitative precedence

is granted *a priori* to cognitions relative to psychological characteristics over cognitions about social attributes, or vice versa. Hence, the present approach treats as problematic and researchable the ways in which categorizations in terms of social attributes and psychological characteristics contribute, in a given situation, to the identifying act. The tentative theoretical framework proposed below constitutes a means of studying the identity-construction process that does not involve any assumption as to which category types *necessarily* form the organizing core around which identity is elaborated. Instead, the framework focuses the attention on the critical problem of specifying under which conditions certain categorizations are most likely to take place.

With Bruner (1957:148), identity is viewed here as representing the range of inferences about properties, uses and consequences that can be predicted from certain cues acting as signals of category membership. In this view, which is highly consistent with Mead's (1934) treatment of object as plan of action, the other's identity is not intrinsic to him. Identity is constructed in a tentative way by the perceiver "in-situation," and it may undergo

* I am deeply indebted to Professors D. P. Cartwright and T. M. Newcomb for generous advice and criticism.

subsequent revisions through an ongoing categorizing process (Turner, 1968).

Furthermore, in the context of this paper, identity construction is considered as a matching process between observed behavior and categories made available to the perceiver through social processes. Consequently, cases in which identity construction does not involve observation of behavioral events are not dealt with.

Behavior observed in a particular social context supplies information to the perceiver concerning the attributes that might be imputed to the other. Identity construction invokes attributions.

Interpersonal attribution processes play a central role in both Heiderian (Heider, 1958; Jones and Davis, 1965; Kelley, 1967; 1972) and interactionist (Mead, 1934; Turner, 1956; 1962; 1968; Strauss, 1959; Goffman, 1959; 1961; McCall and Simmons, 1966) positions. This similarity of scientific interest generally has been overlooked by most researchers who belong to either social psychological tradition (a notable exception being Alexander and Epstein, 1969). As a result, both approaches have remained largely alien to each other as evidenced by a scarcity of cross-references. In a way, the present contribution may be seen as an attempt to reduce the gap between these theoretical positions.

In the first part of this paper, attention is focused on some specific aspects of the Jones and Davis (1965) analysis of the attribution process in person perception which constitutes an influential attempt at systematic theorizing in the Heiderian approach (see, for example, Hastorf et al., 1970; Shaw and Costanzo, 1970; Steiner, 1970). More specifically, attention is centered on the problem of "personal" and "role" contributions to person perception as well as on the manner in which Jones and Davis portray the perceiver.

The second part is devoted to a brief consideration of Turner's conceptualization of role-taking and to contrasting Turner's representation of the perceiver with that of Jones and Davis. The critical comments formulated in the first two parts serve to introduce the tentative framework in the third one.

It should be borne in mind that these

critical comments are not criticisms of the theories put forward by these authors. Neither Turner nor Jones and Davis address themselves to the question of identity construction per se. However, they do deal with concepts and processes that are of central importance to this subject matter; the role concept and the representation of the perceiver's situation are cases in point.

The Jones and Davis Conceptualization of In- and Out-of-Role Behaviors

Attribution theory (see Jones et al., 1972 offers a broad survey of the field) has developed within social psychology primarily around Heider's (1958) influential book, *The Psychology of Interpersonal Relations*. For Heider, man understands his world by referring transient behavior and events to relatively stable underlying conditions or "dispositional properties" which force - people and events to manifest themselves in certain ways under certain circumstances. Central to Heider's position is the assertion that man perceives events as being caused. Of critical importance for the interpretation of the social world is "the separation of the factors located in persons, and those that have their source in the environment of these persons" (Heider, 1958:297), i.e., the distinction between perceptions of internal and external causality. Attribution, "the linking of events with their underlying conditions" (Heider, 1958:89) involves, thus, the use of information in making causal explanations.

Making some simplifying assumptions in Heider's model, Jones and Davis (1965) analyze the process of attribution in person perception by focusing on the specific attributions to the person (internal causality) used to explain behavior. The authors define the task of the perceiver as one of inferring another person's intention from his action; the inferred intention may, in turn, be regarded as indicative of the existence of a dispositional property. By implication, the personal property ultimately can account for the other's action.

The dichotomy person-environment that is found in Heider's model becomes,

in the Jones and Davis analysis, an opposition of polar factors such as personal-social, deviant-typical.

Actually, the opposition of such factors results from the manner in which the perceiver's orientation toward the other and his social environment is conceptualized. Jones and Davis seemingly attribute to their perceiver a proneness to divide the conduct of the other into what Goffman (1961:152) calls a profane and sacred part. The profane part is attributed to the obligatory world of social norms; it is formal and exacted by society. The sacred part has to do with "personal" matters, with what the other is "really like" as a person. In this view, the perceiver is portrayed as a naive psychologist for whom personality is a closed system which society "impinges upon" but does not structure. His task is defined as that of inferring the other's personal dispositions.

For the perceiver who is directed toward the other and his psychological processes, and for whom personal is opposed to social, the other's *deviant* behavior constitutes an indispensable datum for inferring personal characteristics. However, such inferences can be made only to the extent that the perceiver views deviant behavior as stemming from the operation of psychological processes immune from any "social" contamination. Otherwise, the possibility exists that the other's behavior, instead of being seen as a "personal" manifestation of irreverence toward some norm, might be viewed, say, as expressing the other's commitments to some counternorms of a particular group. Hence, it becomes understandable why Jones and Davis place the perceiver, or the other, or both, in situations where the perceiver views his social environment, or the environment in which the other's action takes place as a coherent and well-integrated social system. It is in those *atypical* situations (Buckley, 1967), in which clear knowledge of consensually-defined and shared norms prevails, that the perceiver is virtually compelled to explain deviancy in psychological terms. The role context devised by Jones et al. (1961) illustrates the point.

The concept of role espoused by these researchers is Lintonian (Linton, 1936) in

that they consider as given the existence of distinct roles characterized by clearly established role expectations. Their treatment of role which "stresses the shaping of individual responses by social expectations or externally imposed norms" (Jones, Davis and Gergen, 1961:302) entails a strong cultural and mechanical determinism. It is under such conditions, which presuppose rigid role boundaries, that in-role and out-of-role behaviors can unequivocally be distinguished; and according to Jones and Davis, (1965:234) "behavior which conforms to clearly defined role requirements is seen as uninformative about the individual's personal characteristics, whereas a considerable amount of information may be extracted from out-of-role behavior."

Consistent with their treatment of role, these authors tend to represent in-role behavior as actions mechanically enacted in identical ways by all accepting performers. In this manner, they exclude virtually all possibility for in-role behavior to be informative about the other's personal attributes. As a result of their oversimplified approach to role functioning, questions such as that raised by Hasterof et al. (1970:90), as to how people communicate true positive feelings when positive behavior is role-required, cannot be answered. Furthermore, as in that theoretical approach where attributions of personal dispositions are reduced to attributions of deviant characteristics, it would appear that only deviant behavior could contribute to identity formation.

At this point, it should be borne in mind that different people may, indeed, enact a given role in distinctive and expressive ways which may be informative about personal characteristics. Furthermore, roles involve expectations for personal qualities as well as for behavior and, therefore, contribute to definitions of identity. In a similar vein, it is worth noting that positions are socially evaluated, for example, in terms of their utility, prestige and legitimacy and they differentially evoke interest, respect, hostility, etc. Consequently, for any individual, the mere fact of being the incumbent of a particular position entails that personal characteristics are *ipso facto* attributed to him.

In postulating the personal-social dichotomy as having the thickness of reality for the perceiver, Jones and Davis bypass the important problem of identifying the antecedent conditions under which the perceiver does oppose personal to social. There are, indeed, countless situations in which people do not oppose these terms in any radical way. For instance, in the Steiner and Field (1960) study, expressing a segregationist position could be regarded by subjects as indicative of "personal" dispositions, although such a viewpoint is "social" in nature, even for college students.¹

These brief considerations deal with common situations in regard to which the Jones et al. (1961) conception of role has limited validity. In numerous cases, the other's conduct does not seem to lend itself to immediate categorization in terms of personal and social aspects, and those characteristics which may be inferred from in-role behavior are not necessarily less "personal" than the ones that may be imputed from any other behavior. From the *perceiver's vantage point*, "in-role" behavior may be informative about the other's personal characteristics, and its informational value may even be crucially important to the perceiver *in situation*.

The conceptualization of "out-of-role" behavior can be examined along the same lines. According to Jones, Davis and Gergen (1961:303) out-of-role" behavior, or departure from role expectations "suggests a pattern of motivation and skill that is at variance with specific role requirements." Out-of-role behavior emerges because personality overrides role expectations and, consequently, conveys information about the other's personal characteristics.

It should be noted, though, that for

out-of-role behavior to be expressed, the other must be participating in role relationships. From the perceiver's viewpoint, out-of-role behavior may, indeed, achieve meaning by virtue of its being embedded in a role context. In such cases, instead of being viewed as an irrepressible manifestation of the other's "true self," such a behavior may be apprehended in contemporary relational terms. For example, in clear contrast with the Jones et al. (1961) contention, according to which out-of-role behavior should generate confident inferences about personal characteristics, subjects in Ring's (1964) study did not know what to make of behaviors departing from status expectations.² Moreover, a number of subjects tended to interpret such out-of-role behaviors so that they could become appropriate or meaningful in terms of contemporary role relationships (e.g., as strategy).

By virtue of the fact that out-of-role behavior has to be performed while the other occupies a position, the perceiver may possibly come to make judgments from such a behavior concerning the other as a particular *performer* of the role. Accordingly, the "pattern of motivation and skill" at variance with specific role requirements would then generate inferences about the other *qua* performer instead of being viewed as the sacred part of his conduct (Sarbin and Allen, 1968:490). In a related perspective, it is conceivable that the perceiver might regard the other's behavior as suggesting that the other has some measure of disaffection from, or resistance against his role. Such a separateness between the individual and his putative role is called "role distance" by Goffman (1961:108). In this case, the other may be viewed as actively withdrawing from the self-image which is available for anyone entering the position in question.

¹ In that study, groups of three college students were asked to discuss the question of social desegregation. In half of the groups, a confederate of the experimenter was publicly assigned the role of a "typical Southern segregationist"; in the other groups, no roles were assigned. Results showed that both Ss in no-role groups and Ss in role-assigned groups judged the accomplice to be a strong segregationist. Ss were not found to reject him more completely in the former groups than in the latter ones.

² Ring investigated situations in which a high-status person (or a low-status person) presents suggestions, opinions and a request for a favor to a low-status person (or a high-status person) who responds either favorably or unfavorably. Results suggested that Ss viewed the compliant high-status person and the non-compliant lower-status person as behaving in a way inappropriate to their status, which generated uncertainty and suspicion.

For instance, the other's behavior ("out-of-role" in the Jones et al. [1961] perspective) might be perceived as reflecting his attachment or commitment to another role, and out-of-role behavior (role A) would then appear as in-role behavior (role B).

Actually the issue is not whether role distance *is* out-of-role behavior but, rather, whether the perceiver in-situation views out-of-role behavior as, say, role distance. How the perceiver comes to define such behavioral manifestations the way he does is an empirical question which cannot be studied experimentally unless some provision is made to record perceivers' own definitions, be they psychological or nonpsychological in nature. To illustrate, it might be tempting to speculate on the number of subjects assigned to the Submariner-Inner condition of the Jones et al. (1961) study who did view the interviewee's behavior as an expression of his inferred antimilitarist position.³ Since, in that study, subjects were presented only with impression rating scales on which they had to indicate what they thought the interviewee was "really like" (i.e., forcing subjects to view out-of-role behavior in psychological terms, that number remains unknown (see also Alexander and Epstein, 1969).

These remarks, formulated with regard to the Jones and Davis approach to in-role and out-of-role behaviors, point to the need for an inclusive role concept. Such a concept should be compatible with the fact that in-role behavior may provide the perceiver with information about the other's personal characteristics, while out-of-role behavior may be regarded as

role performance. Turner's conceptualization of role appears to meet that need; some very specific aspects of his approach to role-taking are discussed in the following section.

Turner's Approach to Role-Taking

Turner (1956) adopts an action framework in which he examines the dynamic interrelations among the elements operating at a given time to determine action. He argues that role-taking designates a kind of relationship which may be assumed contemporarily toward a relevant other in the context of an act in progress. In this view, role-taking is a process of looking at another's behavior by viewing it in the context of a role imputed to that other.

This process of placing specific actions in the context of the entire role of which they are assumed to be a part requires that the role of the other be either identified or constructed. Turner (1956:317) cites several ways in which the individual may conceive the other's role among which the following one is particularly relevant to the present discussion: role-taking "may proceed from observing a segment of behavior to identifying the feelings or motives behind the behavior. . . ." Thus, Turner views as a central characteristic of role-taking the process of discovering and creating consistent wholes out of behavior, i.e., the grouping of behavior into units or roles. Roles become points of reference for placing interpretations on, and making evaluations of individual actions.

In Turner's treatment, the concept of role is conceived more inclusively than in the Jones et al. (1961) approach. By role, Turner (1956:316) means a collection of patterns of behavior which are thought to constitute a meaningful unit and deemed appropriate to a person occupying a particular status in society, occupying an informally defined position in interpersonal relations (e.g., compromiser) or identified with a particular value in society (e.g., patriot). The term "appropriate" purposely is left without referent by Turner who stresses the fact that what is regarded as appropriate will vary depending upon

³ In that study, Ss listened to recorded "job interviews" knowing that the interviewee had been instructed to make a good impression on the interviewer in order to qualify for the job. Some Ss heard the interviewee scrupulously play his assigned role (i.e., he presented himself as "other-directed" when applying for the job of submariner or as "inner-directed" for the job of astronaut) whereas others heard the interviewee respond to questions with statements indicating he lacked the personal qualifications required for the job (the submariner-inner and astronaut-other conditions which thus involved out-of-role behavior). Results indicated that out-of-role interviewees were perceived to be revealing their true character more than in-role interviewees.

the vantage point of the person formulating the role conception. In this broadened version of the role concept, Turner expands the limits of the domain to which it can be applied. "Emergent" roles (Newcomb et al., 1965), interactive roles (McCall and Simmons, 1966), situated roles (Goffman, 1961), conditioning roles (e.g., sex, age and ethnic group roles) can now be considered too, in addition to roles, as traditionally handled by role analysis (organizational, occupational roles).

Information derived from observing behavior thus is regarded both in the Turner approach and in the Jones and Davis analysis as being processed to infer intentions, purposes or motives. Whereas in the former treatment the assignment of intention is considered as a phase in the identifying process of the other's role, in the latter it is asserted that the attribution of intention may be used to infer "those underlying stable characteristics toward which the perceiver presses in attaching significance to action" (Jones and Davis, 1965:222).

Basically, behavior becomes meaningful action in ways that differ depending upon how the perceiver's perspective is conceptualized. In Turner's (1962:24) approach, attention is focused on the immediate functionality of imputations of role attributes for a social act in progress. The perceiver is represented as a kind of naive role analyst to whom behavior makes sense when "a series of actions is interpreted as indicating that the actor has in mind some role which guides his behavior." Whereas Turner's (1962:22) emphasis is placed on a postulated "tendency to shape the phenomenal world into roles," Jones and Davis (1965:220) primarily stress the importance that people attach to understanding persons as causal agents. As noted above, they portray the perceiver as a naive psychologist whose cognitive task "involves processing available information about, or making assumptions about, the links between stable individual dispositions and observed actions."

Such a difference in the conceptualization of the perceiver's perspective does not stem logically from the adoption of

different levels of analysis by these authors. Actually, what is at stake is the phenomenal experience of the perceiver, and how behavior becomes meaningful action is an empirical question. The perceiver is in-situation and the manner in which he defines his position there, his problems at hand, affects his inferential activity. Hence, the question as to whether some behavior is informative cannot be tackled properly unless the vantage point of the perceiver in-situation is taken into consideration. In accordance with this general assertion, a theoretical scheme is outlined in the following section. It provides a basis for studying the identity construction process which is broad enough to encompass potentially-diversified inferential activities.

Identity Construction: A Tentative Theoretical Framework

Anticipating what follows, it is necessary to indicate that the present theoretical framework does not constitute some kind of "resolution" between the Turner and the Jones and Davis positions; nor is it a conversion of the Jones and Davis conceptualization of in-role and out-of-role. The problem that the framework addresses is not what the perceiver is or is not able to infer about the other's personality but, rather, under which conditions the perceiver in-situation comes to view the other as a performer of role(s) or as a person endowed with distinctive personality characteristics which explain action.

According to the framework, the perceiver's perspective is treated as variable in time and across situations. *At any given time*, the perceiver's construction of the other's identity is characterized by either one of two perspectives: "performer" and "person" perspectives which will be explicated below.

It is because of the definite influence which the early stages of the categorization process have upon the subsequent ones that, here, identity construction is examined in the particular case where the other (O) is a stranger to the perceiver (P). However, the framework does also apply to situations in which O is not, or is no longer a stranger to P.

The entire framework rests upon the following hypothesis: It is assumed that P may *initiate* his construction of O's identity by following either one of two inferential paths which form an "initial branching." The initial branching constitutes a dichotomization of the *early stages* of the identity-construction process made in terms of a differential emphasis placed upon certain cues selected and used by P to make inferences. (Categorizations may proceed on the basis of information derived from observing behavior in a given situation as well as prior information such as knowledge about the social context in which O is viewed.)

Along the first inferential path of the initial branching, P may be said to be viewing the other *qua* performer when behavior is looked at in the context of a role imputed to him. O's identity, as P constructs it, derives essentially from the whole scene of O's actions as they are seen meshed in specific role relationships in a particular interactive situation. Viewing the other *qua* performer presupposes that O's role has been recognized or constructed. Basically, P may arrive at identifying O's role from locating O's position to inferring its role, or P may proceed from observing some behavior and then inferring O's role of which that behavior is assumed to be a part. In the latter case, in trying to discern O's role, P attributes certain motives in the light of which O's sequences of behavior appear as tied together by a certain consistency of direction (Turner, 1956; McCall and Simmons, 1966).

Role imputation is variable as to the number of different roles in a person's repertoire and, consequently, P cannot place O's actions in a role context unless his role repertoire enables him to interpret O's actions as the manifestations of a role configuration. It must be stressed that, in the present perspective, identifying O's role is a necessary but not sufficient condition for viewing the other *qua* performer. O's role must not only be recognized or constructed, but it must also invoke role attributes used for placing O into identity categories.

In judging O's specific performance, P views O's actions against the background

of more or less clearly-defined role expectations held by him. Not only is O expected to perform certain acts, but also he is expected to perform them in specified ways. Following Sarbin and Allen (1968), P may be represented as making inferences as to the appropriateness, propriety, and convincingness of O's specific performance. Moreover, P may come to regard O as being attached to his role, or even embraced by it (Goffman, 1961). Such judgments contribute importantly to identity construction since role-appropriate personal qualities are effectively attributed, i.e., the virtual self that is implied in the stranger's role is imputed to him.

In contrast, the stranger may be seen as portraying a character whose qualities his performance is designed to evoke. Such an inferential outcome reflects a dramaturgical conceptualization of O's behavior. Seen as something enacted (role playing), behavior may appear as being performed with guile ("playing at") or good faith, with or without awareness. In this case, O's performance enables P to assess the stranger's attachment to his role and to what extent he withdraws from the image generated for him by his mere participation in role relationships. It must be emphasized that, regardless of how substantial O's role distance may appear to P, O is seen as enacting a role. Otherwise, P cannot possibly view the other *qua* performer, and his identity construction of the stranger proceeds along the other inferential path of the postulated initial branching.

Along the second inferential path, P may be said to be viewing the other *qua* person, i.e., as an organized entity characterized by a unique configuration of personal attributes. What characterizes P's inferential activity, when he views the other *qua* person, is the assignment of observed behavior to psychological causes internal to O (Heider, 1958; Jones et al., 1972). However, when O's behavior appears attributable to the operation of external forces, P's construction of the stranger's identity is blocked if, indeed, he views him *qua* person. If, however, P regards O as the causal agent, he then may attribute to him certain personal char-

acteristics which may subsequently lead P to infer additional dispositions (Schneider, 1973).

So far, the discussion has focused exclusively on the two types of categorizing possibilities open to P without specifying the conditions under which identification takes place. Indeed, construction of O's identity is not an isolated form of behavior. Therefore, the process cannot be studied unless factors which determine P's perspective, at a given point in time, are defined.

Determinants of Branching

Numerous factors may acquire primary importance in channeling P's inferences along one branching path rather than the other; their potency varies as a function of the particular circumstances under which O's identity is being constructed. The topic under examination is so complex that the present discussion has to be restricted to considering a selected sample of determinants. The principle of selection is predicated on the proposition that constructing the other's identity involves an act of categorization. This proposition is consistent with Bruner's (1956; 1957) work on inferential activity on which the discussion draws substantially.

The initial branching basically reflects a differential use of cues and categories in identity construction. Therefore, factors affecting cue utilization (which cues will be more impressive) and category accessibility (which categories will be more readily available for use) are potential determinants of branching. To illustrate, several of the factors are: P's needs and objectives; his expectancies concerning the likelihood of events to be encountered; the consequences implied by alternative categorizations and their relative value to P; P's preference for certain cues in making inferences; the need for adjusting to situational requirements; and the kinds of cues exhibited.

The channeling influence that P's needs and objectives may have on his inferences derives from the functional relationship which links perception and action (Mead, 1934; Hastorf et al., 1970). Need and interest states force P to be selectively

tuned to seek out relevant information and to perceive those events and objects that relate to achieving his goals. The emerging process of identity construction provides P with direction for instrumental activity in that, for instance, it enables him to anticipate the other's action and to adjust his own behavior appropriately.

In this perspective, it can be hypothesized that, when P's performance of his own role in a given interactive situation is contingent upon the stranger's role, P will tend to view the stranger *qua* performer and will process information accordingly. The demands of his role presumably will determine the selection of particular aspects of the stranger's role behavior for emphasis. It is worth noting that, under such circumstances, the identifying act loses most of its instrumental value outside the bounds of the particular interactive situation. In contrast, the following hypothesis refers to categorizations having greater trans-situational generality. This hypothesis posits that P initially will tend to view the stranger *qua* person whenever he anticipates interacting with the stranger in a situation that does not involve the same type of activity system as the one in which the stranger is being observed. It can be expected that P's construction of O's identity will involve categorizations in terms of personality traits which subjectively constitute generalized response dispositions.

In an experiment reported elsewhere (Guiot, 1975), a series of propositions derived from these two hypotheses was tested. Each subject was instructed to listen to a taped conversation, then to send a message to his teammate concerning the stranger on the tape. The message was composed by selecting four sentences from a list of sixteen pretested sentences describing the stranger from either the "person" perspective or the "performer" perspective. Two independent variables were manipulated. The first was "type of anticipated interaction" (the teammate was going to work with the stranger, either in the "same" type of situation as the one on the tape or in one totally "different" from it). The second was "role distance" (in the taped conversation, the stranger either manifested disaf-

fection from his leader role or did not). It was hypothesized that, irrespective of role distance variations, type of anticipated interaction would induce subjects in the "same" conditions to view the stranger *qua* performer, while those in the "different" conditions would view him *qua* person. The data indicate that type of anticipated interaction was the only significant factor. No significant interaction between this variable and role distance was found, while predictions concerning inferential perspective proved to be correct in all conditions except one.

In the situations just considered, the channeling of P's inferences results from the necessity to adopt a state of preparedness for coping with O and to make interaction more predictable. Similar channeling effects due to P's objectives may result in a large variety of contexts of purposive activity. To illustrate, two cases involving very different types of objectives are briefly considered. The first is one in which the channeling of inferences is a consequence of a technique of interpersonal control used by P. In this case, identity construction can be viewed as a process through which P attempts to exercise control over O by casting him into an identity type that is congruent with P's goals or values.⁴ Most "altercasting" (Weinstein and Deutschberger, 1963) seems to require the adoption of the "performer" perspective (casting O into a role type); however, it may invoke the "person" perspective when attribution of certain personality traits is viewed by P as necessary to promote and sustain interaction in a desired direction (e.g., to generate O's concern with his feelings or needs).

The second case of channeling deals with situations in which P's objectives are anchored in the goals of a group which also involves O. If the group operates under well-defined goals and arrangements of roles for carrying out tasks, then P's objectives will elicit construction

of O's identity from the "performer" perspective by virtue of the interdependence of their activities. However, if objectives and tasks are ill-defined, then the tendency to use O's role as a background against which his behavior is assessed is reduced; hence, P's proneness to adopt the "performer" perspective is reduced as well.

The learned probabilities of occurrence of interdependent events in P's world play a role comparable to need and interest states in inducing certain categorizations rather than certain others (Bruner, 1957). For instance, P's expectancies concerning the likelihood of encountering a particular type of individual in the situation where O appears may trigger and then channel P's inferences along one path or the other, depending upon P's assumptions about the situation.

Identity construction may involve a resolution of expectations about the values of alternative categorizations. Channeling of P's inferences along one path is likely to occur when categorizations along the other path foreshadow less valued outcomes (e.g., damaging consequences for P's self-conception or a costly payoff in case of inadequate identification). In a related perspective, the channeling of inferential activity may result from a search for attributes in terms of which a given situation appears most "balanced" to P (Eiser and Stroebe, 1972).

If the channeling process is looked at from a point of view offered by cognitive dissonance theory (any other consistency theory could be referred to), it can be asserted that those inferences which entail a *reduction* of experienced cognitive dissonance will tend to emerge. Hence, depending upon the concrete situation in which P finds himself, one inferential path may be taken rather than the other. In the same vein, one path may be avoided if it implies categorizations that could *generate* cognitive dissonance. For example, in Ring's (1964) study, the author attempts to explain his data by invoking a stereotype of "status-linkage," i.e., a tendency to view behavior as *consistent* with a person's status.

These general propositions may apply

⁴ Among such values, the perceiver's self-conception (Turner, 1968) may occupy a central position. Constructing the other's identity involves making interlocked categorizations about events and persons including the *perceiver himself*.

to situations in which O is not a stranger to P. To cite one example, it may be that the identity implications of O's actions could engender cognitions dissonant with prior knowledge about O if P were viewing the other *qua* person; hence, P's adoption of the "performer" perspective.

Preference in cue utilization also can enter into determining which path of the branching will be followed. Certain cues may be used predominantly by virtue of their discriminatory value demonstrated in past categorizing situations, their face validity, their linguistic codability, etc. Systematic preference which may stem from P's professional training or his having developed some interpretative scheme of human action in general (e.g., from an ideology emphasizing an individualistic conception of social causation) similarly can orient the inferential process.

Besides preference in cue utilization, it is worth noting that certain cues may be registered preferentially because of situational demands exerted on P. Time pressure, for instance, tends to increase the salience of immediately available cues in making categorizations. Under such conditions, discerning the other's role in an interactive context might be precluded if it requires a search for subtle attributes.

Finally, P's perceptual selectivity may emphasize certain cues that permit an accentuation of the differences between the people encountered in a given situation (Bruner and Perlmutter, 1957; McGuire and Padawer-Singer, 1976). To illustrate, when O is the odd man out in a social context (e.g., the only teenager), attention tends to be focused on him not as a person but as an occupant of a position. As a result, the odd man is likely to be viewed *qua* performer and his behavior seen as role performance.

Some Additional Comments

To conclude the presentation of the framework, it is necessary to stress the following points that have been treated as implicit.

First, adoption of one inferential perspective may or may not result from a conscious decision on the part of P. Often an unconscious process, categorizing may

become conscious, for instance, because of disconfirmation of expectations or emergence of a problematic situation.

Second, identity construction is an ongoing process which, at any given time, can be characterized by either the "performer" or the "person" perspective. Activation of one perspective is assumed to suppress the *simultaneous* adoption of the other perspective because each rests upon a distinctive organization of information. Several experiments in the field of perception have demonstrated similar phenomena (see, for example, Leeper's classical experiment cited in Hastorf et al., 1970).

Third, the postulation of an initial branching *does not* preclude the possibility that, once an inferential path is taken, inferences along the other path can be made *subsequently*. Inferences made from one perspective may instigate, or fuse with inferences drawn from the other perspective.⁵

Fourth, because the present approach has focused heavily on the *initial stage* of identity construction, it has devoted little attention to later stages in which identity is being tested, negotiated and revised mainly through interpersonal communication. This approach, however, is entirely compatible with the notion that identity is socially constructed.

Fifth, the postulation of an initial branching entails a definite differentiation in the way identity construction is initiated and evolves from there. For example, in an unpublished study, a number of stories, each describing a brief social interaction, were presented to respondents who were asked to indicate what they thought of the focal person. Depending upon the nature of their inferential perspective (assessed by independent judges), respondents described the focal person in very different ways. To illustrate, a story involved a sergeant, a private and a captain (the focal person) who

⁵ Turner's position (1961; 1968) as to the framework of categorization for personality being a derivation from the categorization of roles does not actually contradict the present approach. His approach suggests a relationship between the two branches that, however, is not viewed here as invariable so far as *identity construction* is concerned.

did not intervene when the private was punished erroneously by the sergeant. While some respondents perceived the captain as being unfeeling, a "heartless creep" (the other *qua* person), others saw him as thoughtful, doing the right thing (the other *qua* performer). To those respondents who did not have an "appropriate" military role repertoire, viewing the captain *qua* performer virtually was forbidden since they could not realize that the captain, in that situation, was following military rules.

Another story portrayed a teenaged son engaged in heated conversation with his mother. For some respondents, the placement of his behavior in the context of a role typically performed by teenagers in relation to their mothers did not occur (the other *qua* performer); they viewed him as being insensitive, unable to compromise (the other *qua* person).

Thus, these stories (among others) triggered divergent categorizing activities, the outcome of which could then be interpreted parsimoniously in terms of the suggested framework.

Summary and Conclusion

According to the framework outlined in this paper, at any given time P's construction of O's identity is characterized by either one of two inferential perspectives. While viewing the other *qua* performer entails the attribution of role-relevant qualities from observing behavior as specific role performance, viewing the other *qua* person involves the assignment of observed behavior to psychological causes having their origin in O's personality.

Of considerable importance for the kinetic study of the identity construction process is the case where O is a stranger to P. In that case, an initial branching constituted of two inferential paths potentially open to P is postulated. These paths correspond to the two inferential perspectives which ultimately reflect a differential emphasis placed upon certain cues selected and used by P as a basis for inference.

Although this framework has been introduced by referring to the Jones and

Davis analysis of attribution processes and the Turner treatment of role-taking, it obviously should not be regarded as a "resolution" of these theoretical positions. Actually, some aspects of both approaches have been examined and contrasted to underline the necessity of using a role concept for person perception studies inclusive enough to account for diversified categorizing activities.

In emphasizing the importance for identity construction of an inferential perspective by which P views the other *qua* performer, the present approach can deal with those common cases where P does not divide O's conduct into "personal" and "social" parts. It fully recognizes and accommodates the fact that traits or dispositions represent only one type of person concept (e.g., Little, 1967; Peevers and Secord, 1973). As shown earlier, viewing the other *qua* performer might generate inferences about O which could not possibly be derived if P were viewing him *qua* person.

One implicit assumption underlying most research in person perception is that P's inferential set is immutable; that is, he invariably views O as a self-contained entity whose actions reflect internal states and processes. What generally has been overlooked is the question of identifying the circumstances under which P behaves in the manner hypothesized. Postulating the existence of two inferential perspectives, the present approach addresses the problem of specifying conditions which, at a given time, determine P's perspective. Several factors have been mentioned as variables that might be invoked to account for, or to predict the nature of P's categorizing activity. Most of these factors indicate the imperativeness of considering the vantage point of P. Unless this basic requirement is met, the question as to whether a given behavior is in-role, out-of-role, or whatever, cannot properly be tackled except in rather atypical situations. Neither can its informational value be assessed. In the proposed framework, perceivers are not represented as undifferentiated entities juxtaposed to an environment defined in universal terms. Placing the emphasis upon the constitutive relationships between P and his

environment, this approach treats identity-construction processes in an action context where time is a factor.

The foregoing discussion intentionally has been confined to a conceptual outline. Nevertheless, some broad lines of research have been suggested from which empirical statements can be derived. In order to make predictions about inferential outcomes, a number of specific considerations must be taken into account depending upon the particular research interest. A major problem inherent in the suggested approach lies in the difficulty of defining P's vantage point. For example, what constitutes appropriate role behavior depends on P's role conception, hence the importance of gaining access to it. Although such empirical problems are not insoluble, they clearly must be resolved if the present approach were to be adopted.

Experimental work in the different lines of research that this tentative framework suggests will undoubtedly necessitate its reformulation. As it stands, it addresses important issues in identity construction that have not yet received the attention they deserve.

MARITAL STATUS, LIFE-STRAINS AND DEPRESSION

LEONARD I. PEARLIN

National Institute of Mental Health

JOYCE S. JOHNSON

U. S. Department of Labor

American Sociological Review 1977, Vol. 42 (October):704-715

The relationship between marital status and psychological distress, consistently documented by a variety of studies, traditionally has been interpreted as reflecting the unmet inner needs and emotional frustrations of never married and formerly married people. In contrast, the present study examines the depressive consequences of economic hardship, social isolation and parental responsibilities as three durable, structured conditions of life to which unmarried people are both more exposed and more vulnerable.

Occasionally important relationships between social structural factors and mental disorders are discovered far in advance of our learning how these relationships are forged. This has been the case with regard to the psychological impact of such fundamental features of social organization as social class (Kohn, 1972; Mechanic, 1972) and sex roles (Gove, 1972; Gove and Tudor, 1973; Pearlin, 1975) as well as for marital status, the concern of this report. For many years, at least since Durkheim's (1966) work, it has been recognized that the unmarried are more disposed than the married to emotional problems. There is now an accumulation of studies showing with rare, though not perfect (Dupuy et al., 1970), consistency that people with spouses are more likely to enjoy psychological well-being than those without

(Blumenthal, 1967; Bradburn, 1969; Briscoe and Smith, 1974; Gurin et al., 1960; Knupfer et al., 1966; Radloff, 1975; Srole et al., 1962).

Although there is relatively little research aimed directly at understanding how these differences arise, three major explanatory themes can be extrapolated from existing writings. The first, discussed by Bachrach (1975:6-7) in her extensive review of the literature, pertains exclusively to the formerly married. It views the very transition from marriage to singleness as a stressor event entailing a variety of psychic traumas. Self-conceptions may be assaulted in the course of becoming single, social networks often become unravelled, and established habit patterns frequently must be abandoned. It also has been suggested

(Hunt, 1966) that the formerly married have the difficult task of accommodating to the new role definitions that are more ambiguous than those that gave meaning and direction to their behavior as married men and women. Sexual problems, too, may be especially severe for those newly single who had been accustomed to sexual gratification (Bell, 1966). But regardless of the particular problem identified by different observers, each emphasizes essentially the same process: becoming unmarried is itself a condition imposing difficult and often unclear demands for change, and it is these demands that lead to psychological disturbance.

A second interpretation, perhaps less convincing now than in earlier years, attributes the psychological distress of the unmarried to the powerful norms defining marriage as the most desirable state adults can attain. According to this view, the single who remain single are moving against the grain of these norms, eventually running the risk of being treated as people either unwilling or unable to conform to accepted practice. They are considered as being outside the normative pattern of living (Lee, 1974; Udry, 1974; Gurin et al., 1960) and come to be seen as unfit and deviant. Their disposition to psychological problems, therefore, is a consequence of being objects of contempt because of their failure to conform to prized norms.

Finally, it has been proposed that the psychological problems of the unmarried are not a consequence of their marital status but, rather, a cause of it. This explanation argues that people who are depressed or who suffer other personality debilities are selectively less able than others to be married and to stay married. Such an interpretation is especially favored by epidemiologists and clinicians who have observed the disproportionate number of unmarried people among those suffering from psychoses (Ødegård, 1946; 1960; Malzbert, 1964; Garfield and Sundland, 1966). Because interpretations of selectivity usually are made from observations of psychiatric populations, we cannot be sure how applicable they are to more representative populations. Nevertheless, while such interpretations may be

limited in their generality, they underscore the difficulties in determining whether the marital status or the onset of the psychological disturbance comes first (Bachrach, 1975:2-3).

The present analysis emphasizes the stress-provoking problems of daily life which, with rare exception (Warheit et al., 1976), are ignored by prevailing perspectives. A comprehensive understanding of the relationship between marital status and mental functioning must recognize more than transitional traumas, normative violations and the possibility of psychological selectivity. The part played by structured, persistent life-strains also must be considered. Three such conditions concern us here: the economic resources of people, isolation from social networks, and parental responsibilities. We shall see that these conditions do, in fact, contribute to differences in the psychological functioning of the married and the unmarried, because the unmarried are more frequently exposed to them and are more vulnerable to their effects.

Background and Methods

The data presented here are part of a larger investigation into the social origins of personal stress and were gathered through scheduled interviews with a sample of 2,300 people representative of the population of the Chicago area, which includes sections of Northwestern Indiana as well as some of the surrounding suburbs. A cluster sampling technique was used, each cluster consisting of four households per block. Since the total sample of 2,300 was to be made up of clusters of four households, the interviewing was done in 575 blocks, one-fourth the size of the sample. The 1970 census (U. S. Bureau of the Census, 1972) reports that there are 2,137,185 households in the Chicago Urbanized Area and when this total is divided by the total number of blocks in which households are to be chosen (575), the result (3,716) is the skip-factor for the selection of households. After each 3,716th household was selected, three additional households from that block were chosen by dividing the total number of households on the block

by four and using the result as the factor for counting from the initially selected address. In anticipation of refusals—30 percent of those contacted—and to make allowance for households where contact could not be established within three call-backs, substitute addresses in each block were also pre-listed. The sex of the person to be interviewed in each household was pre-designated in order to have as equal a number of males and females as possible. Finally, only those between 18 and 65 were included, producing a sample still actively engaged in occupational life.

The interview dealt extensively with the strains experienced by people—the conflicts, frustrations and threats that earlier exploratory interviews revealed to be quite common. It particularly focused on strains occurring in the roles of occupation, marriage, childrearing and economic life. Second, the interview sought to identify the coping repertoires people employ in dealing with the strains they experience in these roles. Third, it inquired into people's emotional stresses and their symptoms of disturbances such as depression and anxiety. The present analysis, while focusing on marital status, includes information from a number of different areas covered by the interview.

Depression

Although fundamentally we are interested in the relationship of marital status to all manifestations of emotional well-being and distress, we shall limit our examination to depression. This is partly for ease and partly because it is a state experienced to some degree by everyone under ordinary conditions of life. Indeed, it has been described as the "common cold of psychiatric practice" (Silverman 1968:131). Its commonness suggests that it may be a fairly sensitive psychological barometer of life-strains, and it is largely for this reason that it is selected for use here. But it is important to recognize that depression is only one of several indicators of distress that are related to marital status. Thus, measures of anxiety, happiness, psychosomatic disturbances and self-esteem each are associated with marital status at a level of statistical

significance. Our emphasis on depression, therefore, should not obscure the fact that marital status also is relevant to other dimensions of well-being and distress.

The measure of depression adopted for use here, developed by Lipman et al. (1969) and Derogatis et al. (1971), asks respondents the frequency with which they experience each of eleven symptoms.¹ It should be emphasized that such items are not suitable for the identification of clinical depression among people residing in the community. Although the scales are constructed from symptoms reported by patients in clinical treatment, they cannot be employed as diagnostic tools in field studies. Scores on these measures serve only to reveal an order among people based on the number and intensity of symptoms they experience.

Marital Status and Depression

For much of our analysis, two groups will be delineated: the married and the unmarried. However, in order to show the pivotal relationship between marital status and depression in greatest detail, Table 1 further subdivides the unmarried into the widowed, the divorced and, although they are still legally married, the separated. The results clearly show that the presently married are most free of depression, the formerly married are most burdened by it, and the never married fall squarely between these extremes. Among the groups making up the formerly married category, the separated are outstandingly most susceptible to depression, with no appreciable difference existing between the divorced and the widowed.

Because several important social characteristics are associated with marital status, the relationship between marital

¹ Respondents were asked to reply "never," "once in a while," "fairly often," or "very often" to the following items. During the past week how often did you: lack enthusiasm for doing anything? have a poor appetite? feel bored or have little interest in things? lose sexual interest or pleasure? have trouble getting to sleep or staying asleep? cry easily or feel like crying? feel downhearted or blue? feel low in energy or slowed down? feel hopeless about the future? have any thoughts of possibly ending your life? feel lonely?

Table 1. Marital Status and Depression (Percent)

 $p<.001$.
 $\text{Gamma}=.26$.

status and depression may be spurious, shaped not by marital status but by its attendant social characteristics. Sex, age and race are particularly implicated in this regard, for each of these characteristics is differentially distributed among the marital statuses. For example, women and blacks are markedly overrepresented in all categories of formerly married. With regard to age, the never married have the youngest mean age and, unsurprisingly, the widowed the oldest.

In order to determine if the relationship of marital status and depression persists after taking account of sex, age and race, we have partialled out the effects of these characteristics by the use of gamma. The zero-order gamma between marital status and depression is .26 when the sample is divided into married and unmarried categories. When controlling on the effects that sex has on this relationship, the resulting partial gamma is .22 and when controlling on race and age, the partials are .24 and .27, respectively. The same stability exists, furthermore, in applying these controls separately to the never married, widowed, divorced and separated. In no instance is there an appreciable change in the bivariate relationships existing between the marital statuses and depression when the influences of key social characteristics are taken into account. We can be confident, then, that the results of Table 1 do not spuriously stem from ascribed characteristics that are related to, but different from, marital status itself, for the results persist after the possible influences of such characteristics are removed. Nevertheless, as we observe

some of the conditions that do link marital status and depression, the potential relevance of these characteristics will surface again. Consequently, they will be considered throughout the course of the analysis.

Marital Status and Life-Strains

The life-strains we shall be examining—economic hardships, social isolation and parental role overloads—have in common a resistance to rapid amelioration. They are persistent problems, and persistent problems can have deleterious psychological effects over time. These three life-strains do not account for all of the difference in depression between the married and the unmarried, but they do illuminate how adverse circumstances built into the structure of daily life contribute to the differences. Two mechanisms will be shown to underlie this contribution: differential exposure and differential vulnerability. Each of these will be in evidence as we consider the three life-strains one by one.

Economic hardship. Our evaluation of economic strains relies on a three-part question asking people about their difficulties in acquiring the necessities of life: How often does it happen that you do not have enough money to afford (1) the kind of food you (your family) should have? (2) the kind of medical care you (your family) should have? (3) the kind of clothing you (your family) should have? Each item was answered by "never," "once in a while," "fairly often" or "very often" and a score ranging from 3 to 12 was formed by sum-

ming the values of the three responses. This indicator of economic strain has two advantages over objective income: over 300 respondents could not or would not provide income information, and more important, a given amount of income is not an equivalent resource for families of different size and age composition. Nevertheless, our direct measure of strain is closely related to income, indicating that subjectively experienced strain is rooted in objective economic conditions.

Table 2 divides people according to economic strain, with those scoring 3 being classified as being "free" of strain, from 4 to 6 as under "moderate" strain and from 7 to 12 as experiencing "severe" strain. The column marginals reveal that the unmarried are more likely than the married to experience economic strains: only 73 (5%) of all married people are under severe strain compared to 13% of the unmarried. Correspondingly, 74% of the married are free of strain compared to 55% of the unmarried. Within the unmarried group, the separated experience the most hardship, followed by the divorced, widowed and never married. The table also points to a connection between the intensity of economic strain and the level of depression for, regardless of marital status, the proportions high on depression vary directly with the severity of economic strain. Thus, economic hardship links marital status and depression by (1) being more prevalent among the unmarried and by (2) being a condition disposing people to depression.

However, their greater *exposure* is not the only reason that unmarried people are

more depressed by economic strain; they also appear to have a greater *vulnerability* to the effects of limited resources. This is suggested by comparing the married and the unmarried who are exposed to economic strains of the same severity. The pattern revealed by this comparison appears repeatedly throughout the analysis: the differences in depression between the married and the unmarried are greatest under conditions of greatest strain; as strains diminish, differences in depression among people of different marital status also diminish, although they remain appreciable. These variations in vulnerability to hardship are mirrored in the magnitude of the gamma coefficients under different levels of strain. Whereas we saw earlier that unmarried people are more likely to experience economic deprivation, we see now that they also may be more readily depressed by such deprivation. Both differences are reflected in the relationship of marital status and depression.

Is the effect of economic hardship on the relationship of marital status to depression attributable to extraneous social characteristics? This question is especially pertinent with regard to race; for a disproportionate number of blacks experience severe economic hardships, thus raising the possibility that race more than economic strain is the influential condition in Table 2. However, for blacks and whites alike, the association between marital status and depression is closest under conditions of greatest strain, with the association being reduced appreciably with each reduced level of economic

Table 2. Economic Strains, Marital Status and Depression (Percent)

	Gamma=.43.		Gamma=.24.		Gamma=.17.	

strain. The gamma for this association among blacks under severe strain is .44 and under no strain it is .31; for whites, the corresponding coefficients are .31 and .14. Furthermore, these relationships are found in the same order among men and women, among those less than forty years of age and those forty and over. While there are variations from one group to another in the magnitude of the association, invariably the unmarried, regardless of their race, sex or age, differ most from the married when under greatest strain and the difference is considerably diminished when strain is minimal. Thus, it is economic strain that is the pertinent condition, not race, sex or age.

The same patterns of association emerge when comparisons are made of the married with the never married, widowed, divorced and separated. Except in the case of the separated, where gamma is greater in the "no strain" than in the "moderate strain" category, differences in depression between the married and each sub-type of unmarried are most pronounced where there is most deprivation and are markedly less with improved economic circumstances. Regardless of the circumstances leading to the absence of a spouse, therefore, it is a condition especially likely to be associated with depression under adverse economic conditions.

The unmarried, then, are doubly disadvantaged with regard to economic circumstances. First, they are unequally exposed to a hardship conducive to depression; second, such hardship, even when equally severe among people of different marital statuses, is still more likely to result in depression among the unmarried. Severe economic strains thus are more heavily concentrated in the unmarried population and, in addition, they take a greater psychological toll from the unmarried.

Social isolation. The apparent inability of the unmarried to withstand hardship as well as the married is not necessarily because of a greater psychic fragility on their part. It is equally reasonable to suppose that marriage itself is a barrier standing between outside strain and inner depression. When faced with adversity, married persons may have the advantage of being able to draw emotional support and con-

crete help from their partners. Of course, supportive and helping relations between people are not limited to marriage; unmarried people often establish interpersonal ties that serve as partial functional alternatives to marriage. This suggests that when one has neither a spouse nor surrogate relations one will be especially open to depression.

Several items are indicative of the extent and stability of people's social affiliations. One question asks respondents how long they have lived in their present neighborhoods; another inquires into membership in voluntary associations; and a third asks about the number of "really good friends" who live within an hour's drive. These indicators were pooled to form a measure of isolation from extrafamilial relations. The highest possible score indicates neighborhood residence for less than two years, having either only one or no friends close by, and not belonging to a voluntary association. As judged by this measure, the unmarried are more likely than the married to experience isolation, a result consistent with observations that single people, especially the formerly married, have greater difficulty than couples in establishing a durable and extensive social life (Gove, 1972). Moreover, as the extent of isolation from extrafamilial relations increases, so do the tendencies to depression. Thus, marital status is related to isolation and isolation to depression.

Since isolation is related both to marital status and to depression, it also may be one of the circumstances linking marital status and depression. As in the case of economic deprivations, however, differential exposure alone does not bear the burden of explanation. In Table 3, the married and the unmarried are divided into three groups according to the degree of social isolation they experience. Once again, the findings show the unmarried to be doubly susceptible to depression: first, a larger proportion lives in considerable isolation and, next, they are more likely to be depressed by equivalent conditions of isolation. Indeed, married people are virtually unaffected by isolation from extrafamilial contacts. For this reason, the differences in depression between the

married and unmarried who are considerably or fairly isolated stem entirely from the impact of isolation on the latter. Evidently, the absence of social ties can represent a more complete isolation for the unmarried than for those with spouses, making the depressive consequences of isolation singularly severe for unmarried people.

Again, it is necessary to ask if the results of Table 3 are being shaped by extraneous social characteristics, for blacks substantially more than whites and the older slightly more than the younger are isolated. Both among blacks and whites, isolation is most likely to have depressive consequences for the unmarried. Interestingly, however, the decline in the magnitude of the association with decreased isolation is greater among whites: for this group, the gamma drops from .35 under considerable isolation to .16 where isolation is absent, compared to .35 and .29, respectively, for blacks. Thus, the results of Table 3 arise not because blacks are more often isolated from extrafamilial ties but in spite of their being somewhat less adversely affected by isolation. Moreover, we find that, regardless of the age or sex of respondents, vulnerability to depression is greatest among the unmarried who are separated from social contacts. We can be assured, then, that the relationships in Table 3 are being conditioned by isolation, not by extraneous characteristics associated with isolation.

With regard to the different subgroups of unmarried, it can be noted that there are differences in the degree of isolation

they experience: the widowed are least isolated, followed in order by the never married, divorced and separated. However, when these groups are treated separately, we find in each case that the association between marital status and depression is closest among people experiencing either a considerable or fair degree of isolation, dropping off sharply among those not isolated. Isolation, it can be noted, makes least difference to depression among the separated, many of whom are immersed in the first steps of marital dissolution where the peak emotional crises of this period may overshadow the more low-keyed problems of life.

The absence of a spouse, therefore, is most apt to result in depression when it is in combination with isolation from contacts outside the family. Under any condition, isolated or not, the unmarried are consistently more disposed than the married to depression; but the difference between the two groups is considerably reduced in the absence of social isolation. Being without a mate apparently leaves one open to the depressive consequences of life-strains, especially so when one is also lacking alternative supports.

Parental responsibilities. Economic hardships and social isolation, while seemingly very different conditions of life, have a very important property in common. It is the rather relentless constraints each typically imposes on behavior and experience, the kind of life-strains that remain constant across a range of life-situations. The burdens and responsibilities of parenthood, to which we turn now, also may

Table 3. Social Isolation, Marital Status and Depression (Percent)

impose persistent strains having depressive consequences.

The most direct indicator of parental burdens is the number of children for whom the parent has responsibility. There is one respect, however, in which this feature of parental responsibility is quite different from the other strains we have examined. Although 38 percent of the unmarried people in our sample have the daily care of at least one child, it is the married who are much more likely than the unmarried to have the larger number of children at home. Unlike their greater exposure to economic hardship and social isolation, single people are less exposed than the married to this potential source of strain. If parental responsibilities have a part in the relationship of marital status and depression, therefore, it is not because these responsibilities are more concentrated among the unmarried, but because such responsibilities, where they do exist, are more onerous for the unmarried.

The unmarried do, in fact, have a greater sensitivity to these burdens. Table 4 reveals that as the number of children in the household increases to three or more, there is a corresponding increase in the proportions of unmarried parents who are highly depressed. By contrast, there is a slight tendency in precisely the opposite direction among the married. The net result, reflected in the magnitude of the gamma coefficients, is that the difference in depression between the married and the unmarried having three or more children at home is substantial, while the difference between those having no children

in the household is considerably smaller. Thus, marital status and depression are most closely connected when parental responsibilities are most demanding. The never married who are parents, it should be pointed out, are somewhat more affected by these responsibilities than are the formerly married groups.

Because the social characteristics of people are closely interwoven with the magnitude of their parental responsibilities, it is again necessary to examine their potential part in producing the results in Table 4. Sex is especially salient in this regard, for almost all unmarried people with responsibility for the care of children are women. Only 18 single men have any parental responsibility, four of whom have the care of three or more children. It is difficult, therefore, to separate fully the possible effects of sex from those of parental responsibility on the relationship of marital status and depression. It is instructive, however, to focus on the 18 single men who have responsibility for children. Although few in number, they are entirely similar to their female counterparts, for they are much more disposed to depression than are married men having the same parental responsibilities and more depressed, too, than those men who are also single but free of these responsibilities. Although this is by no means conclusive, it suggests that sex is not responsible for the results in Table 4.

Race, too, is intertwined with the magnitude of parental responsibilities, with unmarried blacks more likely than unmarried whites to have children and to have

Table 4. Number of Children at Home, Marital Status and Depression (Percent)

them in larger numbers. However, when the relationships in Table 4 are examined separately for blacks and whites, the pattern of associations is parallel. Thus, the gamma coefficient for the association between marital status and depression among whites having three or more children is .41 and for blacks with the same number of children, it is .51; for whites with no children, it is .18 and for the corresponding group of blacks, it is .15. Finally, it is the younger parents who are likely to have the care of children at home, making it necessary to distinguish the effects of family size from the possible effects of parental age. When the relationships in Table 4 are examined separately for people younger than forty years and those older, equivalent results appear. The results in the table, therefore, cannot be attributed to race or age or, judging from the 18 unmarried male parents, to sex.

The age of children, like family size, is also a dimension of family composition indicative of parental responsibilities. Briefly, we find that the younger the children in the household, the greater is the association between marital status and depression. The gamma coefficient for this association among parents whose youngest child is five years or less is .48; for those whose youngest child is from 6 to 17, the coefficient is .39; and it declines further to .13 among parents having a youngest child over 18. These age groupings, of course, represent general stages of enlarged self-sufficiency on the part of children and, correspondingly, less constraint on, and more freedom for, the parent who attends his last-born child as he ascends through the age ranks. Thus, depression is most likely to exist among unmarried parents of very young children, the arc of the life cycle in which the burden of parental responsibility is greatest. By the time children reach 18 years and beyond, ages of greater independence, differences between the married and unmarried parents shrink to insignificance. It is apparent that the burdens of caring for young children are felt most keenly by the parent who faces the task alone.

Being a parent, then, entails very different obligations, has very different mean-

ings, and yields very different experiences for the married and the unmarried, regardless of their other social characteristics. The greater the number and the younger the ages of children for whom unmarried parents have responsibility, the greater these differences become. For single parents, the joys of parenthood are most likely to be aroused when the number of their children is small and their ages large.

The Life-Strains: Their Independent and Joint Effects

The foregoing analysis has succeeded in identifying the ways in which some key life-strains contribute to the association between marital status and depression. It is apparent that persistent problems, unequally concentrated among and having an unequal effect on the unmarried, forge the links between marital status and depression. Being unmarried increases one's chances of experiencing hardship and of being psychologically hurt by such experience.

But there are certain issues that remain unaddressed. For example, we have not yet taken into account the overlap that exists in being poor, being isolated and being burdened by parental responsibilities. In order to know the order of importance among these conditions, it is necessary to weigh the effect each has when independent of the others. Second, a direct assessment of the greater vulnerability of the unmarried to life-strains requires that we sort out the interactions of strains and marital status and observe the effect they have on depression in conjunction with each other. Finally, we have not yet dealt with the magnitude of the combined influence of the life-strains on the relationship between marital status and depression. Each of these issues can be dealt with by regression analysis.

Two sets of terms are brought together in the regression equation, the results of which are presented in Table 5; one is made up of the additive terms—marital status and the three life-strains—and the other includes the interaction terms—variables created by joining each of the strains with marital status. The coefficients show the relationship of each vari-

able to depression after the effects of the others are removed. Looking first at the main effects of the additive terms, it can be seen that economic strain is preeminently more important to depression than any other variable. Because, as we saw, the unmarried are much more likely to be exposed to economic deprivation, it is by far the major contributor to the association of marital status and depression. But what about the differential vulnerability of the unmarried to life-strains? Some of the depressive effects of strains were found to be conditional on the marital status of people experiencing them, suggesting that life-strains and marital status jointly produce effects uniquely different from those created by each separately. These effects are captured by the interaction terms which, as shown in the table, are appreciably related to depression, with parental responsibilities in conjunction with marital status being more closely associated with depression than the other combinations. This is consistent with our earlier observation that the number of children is positively related to depression among the unmarried, but is slightly negatively related among the married.

Given that the purpose of this inquiry is to understand why being married or unmarried should make a difference to depression, perhaps the most central issue concerns the extent to which the life-strains have provided this understanding. Our success in this regard can be gauged from the magnitude of the reduction in the relationship between marital status and depression that occurs when the life-strains are taken into account. Thus, the bivariate regression coefficient of depres-

sion on marital status, shown in Table 5, is .206. As can be seen in the table, the coefficient is lowered to .064 when both the main and interactive effects of the strains are separated from marital status. This means that about 69 percent of the original association of marital status with depression is attributable to the differential exposure and vulnerability of the unmarried to the life-strains considered here, economic hardship being foremost among them. The life-strains, therefore, carry most of the burden of explanation, although other conditions remain in marital status that continue to be related to depression.

Overall, being without a spouse is more likely to result in depression when one is also enmeshed in a context of unrelenting strains, especially strains of an economic nature. It is apparent that single people withstand these conditions of hardship less well than do married people. Indeed, marriage is the more beneficial arrangement under all conditions, since being single is somewhat disposing to depression even when strains are absent. Nevertheless, the advantages of marriage are especially apparent when life circumstances are most difficult, not when they are most benign.

Summary and Implications

Few items in the sociological arsenal of information have had a longer history or a more consistent empirical documentation than the differential access to psychological well-being by married and unmarried people. Yet, surprisingly little empirical effort has been made to account for this

Table 5. Regression of Depression on Marital Status, Life-Strains, and Their Interactions (Standardized)

	Regression Coefficients	Standard Error	R ²
Marital Status (MS)	.064	.499	.042
Parental Responsibilities (PR)	.089	.499	.043
Social Isolation (SI)	.056**	.099	.053
Economic Strain (ES)	.231**	.058	.111
PR x MS	.164*	.279	.113
SI x MS	.057**	.089	.117
ES x MS	.043**	.087	.119

* Significant at the .05 level.
 ** Significant at the .001 level.

difference, possibly because the explanations seem so beguilingly self-evident that there is little need to spell them out: the single are open to psychological problems because they are deviant in a society that prizes marriage, because of the traumas they suffer and because of their unmet emotional needs.

While there indeed may be some validity to these views, we sought to learn if the greater disposition of unmarried people to psychological disturbance, depression in particular, also results from their greater exposure to hardship and strain. It was our expectation that when people had to contend with the same life-strains, they then would be similarly inclined to depression, regardless of their marital status. The unequal distribution of hardships provides only a partial explanation, however, for even when hardships are equally severe, their effects are more penetrating among the unmarried. Clearly, it is where one is confronted both by social and economic strains *and* is single that one is most prone to depression. The combination most productive of psychological distress is to be simultaneously single, isolated, exposed to burdensome parental obligations and—most serious of all—poor.

What we have learned suggests that marriage can function as a protective barrier against the distressful consequences of external threats. Marriage does not prevent economic and social problems from invading life, but it apparently can help people fend off the psychological assaults that such problems otherwise create. Even in an era when marriage is often a fragile arrangement between couples, its capacity to protect people from the full impact of external strains makes it a surprisingly stable social institution, at least in the absence of alternative relations providing similar functions.

It should be underscored that it was not our purpose to identify all factors relevant to depression, most of which are beyond the scope of this paper. Thus, as important as they may be, we have ignored personality factors, eruptive events and ephemeral experiences. Instead, we focused on conditions that are durable and persistent, anchored in economic organ-

ization, social relations and family structure. These sorts of conditions deserve to be stressed not because they explain everything we want to know, but because they bespeak the fact that the links between marital status and depression are, in part, shaped by conditions rooted in broad social and economic structural arrangements and are not simply reflections of individual adjustments made on the basis of personality.

SIZE, CENTRALIZATION AND ORGANIZATIONAL ADOPTION OF INNOVATIONS *

MICHAEL K. MOCH
University of Illinois

EDWARD V. MORSE
Tulane University

American Sociological Review 1977, Vol. 42 (October):716-725

This study concerns attributes of organizations likely to facilitate or inhibit the adoption of innovations by organizations. First, it offers an interpretation of the often-found relationship between size and adoption frequency. Second, it investigates relationships between structural attributes—specialization, functional differentiation and centralization—and adoption and it develops a model which specifies interactions between these attributes and the type of innovation adopted. An interaction between size and centralization is also posited, and the model is tested using data gathered from a sample of U.S. hospitals. The findings on the whole are consistent with the hypothesis that adoption of innovations compatible with the interests or perspectives of lower-level decision-makers occurs more frequently in large, specialized, functionally-differentiated and decentralized hospitals. Centralization and the interaction between size and centralization do not appear to affect adoption of innovations which are not compatible with the interests of lower-level decision-makers. Contrary to expectations, the data indicate that functional differentiation facilitates adoption of this type of innovation. A revised model of adoption behavior is suggested, and its implications for a general theory of organizational adoption behavior are explored.

Studies of innovation adoption in organizations have suffered from inadequate conceptualization and from a failure to distinguish among types of innovations. Specifically, despite numerous empirical findings which document a positive relationship between size and adoption behavior (Aiken and Hage, 1971; Becker and Stafford, 1967; Corwin, 1972; Hage and Aiken, 1967; Mytinger, 1968; Mohr, 1969; Rosner, 1968), no clear interpretation has been offered. It is often assumed that size implies availability of the uncommitted resources required for adoption. However, there is little logical explanation for this relationship. In addition, there have been few studies designed to identify differential adoption patterns for different types of innovations. The conclusion frequently drawn is that organizations are either "pioneers" or "laggards" in general, rather than pioneers in some areas and

laggards in others. An approach which distinguishes among innovations types is likely to help explain otherwise inconsistent findings. One such inconsistency involves the relationship between centralization and adoption (Corwin, 1972; Evan and Black, 1967; Hage and Aiken, 1967; Palumbo, 1969; Sapolsky, 1967; Wilson, 1966). While inconsistent findings may be attributed to differences in conceptualizing and measuring centralization, they also may be due to a failure to take the type of innovation into account. It is possible that centralization facilitates the adoption of some types of innovations while inhibiting that of others. This paper distinguishes between two distinct types and empirically assesses their relationships with centralization. It also articulates a theoretical rationale for explaining the impact of size and empirically assesses the direct effects of size on adoption behavior. The findings reported here are limited to the population of non-federal U.S. hospitals; however, these organizations are of widely varying types and have a diversity of structural arrangements. The findings, therefore, provide insight into the processes of organizational adoption in general.

The Implications of Organizational Size

Mohr (1969) has argued that larger organizations, simply because they are large, are unlikely to adopt innovations. Recognizing that size and adoption are often associated, he states that "size itself is not related to innovativeness by logical necessity; it becomes significant only when it implies or indicates the conceptual variables that are important in themselves" (Mohr, 1969:121). Size may indeed have spurious or indirect effects. However, it is also likely to lead directly to economies of scale which enhance the feasibility of innovation adoption. Larger organizations process input in sufficient volume to justify adoption of new technology to accommodate variations in input even when variations occur infrequently. Smaller organizations, however, experience many types of input variations so infrequently that they could not reasonably expect to benefit from making similar accommodations. While Mohr is likely to be correct in believing that size has indirect effects on adoption, it is likely that, conceived as input volume, size has a direct effect as well.

Indirect effects of size may be traceable to its impact on organization structure. As it allows for differentiation in technology, size also allows organizations to more finely differentiate tasks (functional differentiation) and personnel (specialization).

Specialization. Evidence presented by Blau (1970b), Blau and Schoenherr (1971), Child (1973), Hinings and Lee (1971), Meyer (1972) and Pugh et al. (1968) is consistent with the expectation that large organizations are in a better position to employ specialists and formally to differentiate responsibilities assigned to personnel in order to accommodate variation in input material. By employing specialists, the organization gains access to knowledge of new ideas, practices and technical skill (Aiken and Hage, 1971; Corwin, 1972; Hage and Aiken, 1967; Mytinger, 1968). To the extent that both knowledge and skill required to utilize innovations are necessary prerequisites for adoption, organizations with more spe-

cialists may be expected to adopt more innovations when the innovations are compatible with the specialists' needs and interests.

Differentiation. Task or functional differentiation can have a similar impact on adoption behavior. Formally differentiating task responsibilities to organizational personnel focuses their interests within specialized areas. This in turn acts as a constraint on individuals to increase their expertise independently of specialized training while at the same time giving rise to the development of vested interests. Both factors increase intra-organizational pressures to adopt innovations which are compatible with the interests and perceptions of department heads.

Centralization. Besides increasing an organization's access to knowledge and expertise by facilitating specialization and differentiation, organizational size also affects the degree of control top management can feasibly exercise over the decisions and activities of specialized lower-level personnel (Blau, 1970a; Downs, 1967). With increases in size, both financial costs of control and distortions in communication required for control are likely to increase. Wilensky (1967) and Pondy (1970) suggest that with incremental increases in size, control costs increase exponentially to the point where top management is obliged to allocate a portion of its discretionary power. As a consequence, lower-level personnel are in a better position to facilitate the adoption of innovations which suit their needs and interests while resisting those which do not (Coughlan et al., 1972; Wilson, 1966; Zaltman et al., 1973). The degree to which the organization's authority structure is centralized therefore can be expected to be negatively related to the frequency with which organizations adopt innovations compatible with the interests of lower-level personnel.

Innovation Types and Expected Relationships

These considerations lead us to expect positive relationships between adoption

behavior and size, specialization, functional differentiation and decentralization. Innovations helpful to some, however, may be viewed as an inconvenience or even as a threat by others. Organizational attributes which facilitate the adoption of some innovations will not facilitate and may even inhibit the adoption of others. Specifically, functional differentiation, specialization, and decentralization will affect adoption of those innovations which are compatible with the interests or perspectives of specialists or department heads, while having no effect on—and perhaps even inhibiting—the adoption of noncompatible innovations.

Size, unlike other attributes, is likely to facilitate adoption of innovations regardless of their compatibility with the interests of specialized personnel. As noted earlier, greater input volume allows for adoption of innovations which can be employed to process types of material which account for only a small percentage of the total. Since small organizations cannot reasonably be expected to acquire these innovations, size may be expected to lead to adoption regardless of the innovations' compatibility with the interests of specific individuals. Though the indirect effects of size via specialization, differentiation, and centralization may be attenuated by incompatibility, a direct effect is likely to remain.

The considerations outlined thus far lead to the following expectations concerning relationships between structural attributes of organizations and the adoption of innovations which are compatible or noncompatible with the interests and perspectives of lower-level personnel such as specialists or department heads.

1. Size, conceived as input volume, will be positively associated with the frequency of adoption of both compatible and noncompatible innovations.
2. Specialization and functional differentiation will be positively associated with the frequency with which compatible innovations are adopted. They will not be associated, save perhaps negatively, with the frequency of adoption of noncompatible innovations.

3. Centralization will be negatively associated with the adoption frequency of compatible innovations. Its association with the frequency of adoption of noncompatible innovations will be zero or positive.

In addition to these hypotheses, the theoretical perspective suggests the presence of an interaction effect between size and centralization on the one hand and adoption behavior on the other. If, as hypothesized, decentralization facilitates adoption of innovations compatible with the interests of specialists and department heads, its impact should be greatest when top management would incur substantial costs were it to exercise its monitoring and control prerogatives to limit expenditures. As noted earlier, this would be the case in large organizations. Specifically, specialists and department heads may exercise their decision-making discretion in their own interest primarily when top management must incur costs to constrain them. In addition to the three sets of relationships hypothesized above, then, we may look for a fourth:

4. Size and centralization will interact to affect adoption decisions in such a way that compatible innovations will be adopted more frequently by organizations which are simultaneously large and decentralized. Noncompatible innovations will not be adopted more frequently—and, perhaps, even less frequently—by these organizations.

The four sets of hypotheses outlined above represent a rather complex model of organizational adoption behavior. This model posits one main effect (size and adoption), three first-order interaction effects (specialization x compatibility x adoption, functional differentiation x compatibility x adoption, and centralization x compatibility x adoption), and one second-order interaction effect (size x centralization x compatibility x adoption). The goodness of fit between the model and actual adoption behavior was assessed by comparing structural determinants of the adoption of medical and administrative innovations in a representative sample of U.S. hospitals.

The Study

This study is part of a project designed to discern organizational correlates of adoption behavior in a random sample of approximately 1,000 U.S. hospitals. Hospitals were selected for study because they offer variability in several theoretically important areas while at the same time not being substantially different in ways which would preclude measurement comparability and standardization (Perrow, 1965). For example, some hospitals are private and run for profit; others are essentially voluntary associations; still others are public agencies operating under government auspices. Likewise, hospitals are located in areas with varied populations and resources and exhibit a variety of linkages with other organizations (e.g., universities, welfare agencies). Hospitals also show wide variation in the degree of integration, technological complexity, structural differentiation and centralization of decision-making, all of which are considered germane to the study of adoption behavior in organizations (Zaltman et al., 1973). At the same time, hospitals are similar in ways which make them ideal for large-scale comparative study. Measures can be constructed to quantify the relevant variables, and the measures can be standardized to apply equally well to almost all types of hospitals.

Each hospital in the sample was sent two questionnaires, one to the chief medical officer and one to the chief administrative officer. Sixty-seven percent of the medical officers and 68 percent of the administrative officers responded to the questionnaires; and 489 hospitals responded to both instruments.¹ Information on several dimensions was secured from the American Hospital Association to supplement the data base. Since these data were gathered for all hospitals in the sample, it was possible to test for response

bias. Twenty-seven percent of the proprietary (for profit) hospitals returned both instruments, while 52 percent of the voluntary (private) and 49 percent of the local public hospitals did so ($p < .001$). No response bias was found when response rates were compared on the basis of SMSA classification, long- versus short-term facilities, or number of beds.

The independent variables: size and structure. The literature dealing with organizational size has employed many different measures of this concept. Recent works increasingly have employed logarithmic transformations of size to adjust for curvilinearity in relationships between size and other variables (Kimberly, 1976). Logarithmic transformations may be justified on either theoretical or empirical grounds. In the current research, size was taken to be the log of the number of annual patient admissions to reflect (1) input volume and (2) the expectation that the effect of an incremental increase in size on structural variables would decrease as the organizations became larger.²

Using the Directory of Medical Specialties, the measure of the degree of specialization was taken to be the number of each of the 25 medical specialty areas represented on a hospital's staff. The appropriateness of this counting procedure was confirmed by a Guttman Scale analysis which yielded a coefficient of reproducibility of .92.³ A similar measure was constructed to assess functional differentiation. The presence or absence of 14 distinct services available in each hospital (e.g., an outpatient care unit, an emergency unit, an intensive care unit, etc.) constituted the measure of functional differentiation. Services require either dis-

² The correlations between the annual number of patients (logged) and other size measures (also logged) were .81 for number of support personnel, .84 for number of beds and .76 for total noncapital assets.

³ A technique suggested by Upshaw (1968) was employed to test the hypothesis that this coefficient was greater than .90 due to the frequency distribution of responses to the component items. Using this method, this hypothesis was rejected for the measures of specialization, differentiation and adoption.

¹ Thirty-nine of the 489 were operated by the federal government. In terms of resource allocation decisions, these hospitals were actually subunits within larger organizations. To avoid confounding the measure of centralization, therefore, hospitals operated by the federal government were excluded from the sample.

tinct structural divisions or specific personnel assignments (e.g., dental services, premature nurseries, organ banks, etc.). Each service, therefore, represents a distinct functionally-differentiated unit in the hospital. The coefficient of reproducibility for this measure was .91.

The measure of centralization was constructed to reflect (1) the effective, rather than simply the formal, location of discretion and (2) the location of resource-allocation discretion, rather than the discretion to determine procedures. The measure itself was constructed using an indexing procedure which yielded a score reflecting the extent to which each of five specific resource-allocation decisions were made by (1) the hospital board of directors, (2) the chief medical or administrative officers or (3) the heads of medical departments.⁴ Those hospitals in which most decisions were made by the board were considered centralized; those in which most decisions were made by department heads were considered decentralized. Hospitals in which most of the decisions were made by administrative or medical officers were considered moderately centralized. The scores ranged from a high of ten (centralized) to a low of zero (decentralized).

The dependent variables. The innovations studied fall into one of two categories: (1) those which are likely to be sought by organizational specialists and department heads and (2) those which do not directly facilitate their activities and may even be perceived as threatening. It is assumed that, other things being equal, the adoption of new technologies for diagnosis and treatment will be supported by the medical staff. While those responsible for the expenditure of hospital resources—administrators and board members—are unlikely to oppose such adoption, their concerns tend to focus

upon limiting expenses (Rushing, 1974). At the same time, innovations which allow administrators or board members greater control over resource expenditures and personnel are not likely to be sought by specialists and department heads who may even perceive such innovations as a threat to their autonomy (Sapolsky, 1967). Two types of innovations are studied here: (1) the adoption of new medical technology for diagnosis and treatment and (2) the adoption of electronic data processing (EDP) for monitoring and controlling fiscal expenditures and the activities of hospital personnel.

The measure of the frequency of adoption of medical innovations consists of the number of each of 12 new technologies adopted by the hospital. The technologies were selected in consultation with experts in an area central to the delivery of hospital service in general (i.e., respiratory disease). An initial list of 83 respiratory disease innovation items was generated, and these were rated by experts in terms of their initial and current importance, their communicability and the extent to which they represented departures from past medical practice. A literature search also produced ratings on their cost and potential risk to patients. To allow for testing the importance of these characteristics in the adoption process, 11 items were selected which represented diversity in communicability, cost, risk, etc. Despite this diversity, however, a general tendency to adopt innovations regardless of their attributes was confirmed by a Guttman Scale analysis yielding a coefficient of reproducibility of .92. To assess the reliability of this adoption measure, information concerning the presence or absence of each innovation was gathered from both the chief medical officer and the chief administrative officer. The product-moment correlation between the adoption measures based on their independent reports was $r = .78$. In addition, the researchers visited sixteen hospitals to determine for themselves whether the items were present or absent. The correlations between these determinations and the chief medical and administrative officer reports were .86 and .75, respectively. The administrative officers provided additional

⁴ The indexing procedure combined responses from both the chief medical and the chief administrative officers. The decisions involved hiring, supply acquisition and equipment purchasing. High scores were given to organizations in which all of the decisions were made by the hospital board. Low scores were given to organizations in which all of these decisions were made by physicians, almost always department heads.

information from their records concerning the time of adoption as well as the items' presence or absence at the time of the survey. Since it would be difficult to report these data for nonexistent innovations, the administrative officers' responses were taken as the indicator of adoption.

An innovation likely to enhance the monitoring and control capacities of top management was taken to be the adoption of Electronic Data Processing (EDP) for several different functions (Meyer, 1968; Sapolsky, 1967). Though most hospitals had adopted EDP, they varied widely in the diversity of functions for which it was employed. The measure of adoption, therefore, was taken to be the number of functions performed using EDP.⁵

Results

The presence or absence of the expected main effects of structural attributes on adoption was assessed by regressing both dependent variables on size, specialization, functional differentiation, and centralization. In addition, a dummy variable was introduced to test for the presence or absence of the expected interaction between size and centralization.⁶

The data set allowed for controls on several variables which could confound relationships between structure and adoption behavior. Hage and Aiken (1967) and Aiken and Hage (1971) have argued that extra-organizational contacts provide channels through which information concerning innovations may be transmitted. The frequency of such contacts is likely to be associated with both size and adoption

behavior. To allow for this possibility, three controls were introduced: whether or not the hospital reimbursed physicians for travel, the percent of staff physicians traveling at hospital expense, and the percent of staff physicians attending at least one out-of-state meeting during the year. Rosner (1968) has argued that research hospitals are likely to be more innovative than others. They are also likely to be larger and more specialized. To account for this possibility, controls were introduced for the presence of physicians with funds for research in respiratory disease, the presence of laboratory research in the hospital, and the presence of physicians with publications in the area of respiratory disease. In addition, three other controls were introduced. First, hospitals not treating the full range of diseases may be likely to be less specialized or differentiated and more likely to adopt respiratory disease innovations (e.g., hospitals treating chronic respiratory ailments such as tuberculosis). A dummy variable reflecting the general service versus specialty nature of the hospital was therefore included. Second, some hospitals have departments specifically for treating respiratory diseases. Since we were concerned with assessing medical adoption in general, rather than respiratory disease in particular, a dummy variable indicating the presence or absence of such a department was created and introduced. Finally, the presence of at least one other hospital in the area may stimulate adoption either through competition or increased information flow. Controlling for this factor also provided for a general control for rural-urban differences. In all, nine controls were introduced. A stepwise regression procedure was employed to reduce these to a more manageable number. This procedure identified three significant variables which were included as controls in subsequent analysis: (1) the presence of another hospital in the area, (2) the presence of an inhalation therapy department and (3) the presence of physicians with research funds in respiratory disease. Results of the regressions of adoption frequencies on the independent and control variables are presented in Table 1. Taken together, these variables account for 63

⁵ The specific functions performed by EDP involved accounting, admissions, discharges, personnel records, payroll, medical records, research and patient care. All of these functions have direct relevance for the visibility and control of the activities of specialists and department heads.

⁶ Hospitals were divided into three size categories and three centralization categories (nine groups) on the basis of their scores on both size and centralization. Since the expected interaction between size and centralization was expected to occur for large and decentralized hospitals, those scoring in the high size category (N=53) were assigned ones, and remaining hospitals assigned zeros.

Table 1. Adoption Frequency of Compatible (Medical) and Noncompatible (EDP) Innovations and Structural Attributes of Hospitals^a

Cases with Complete Data Independent Variable	Compatible (246)		Noncompatible (245)	
	Beta Weight	p	Beta Weight	p
Size	.18	.005	.18	.043
Functional Differentiation	.15	.018	.21	.017
Specialization	.16	.021	.10	.334
Centralization	-.07	.127	.03	.647
Size × Centralization	.11	.051	-.01	.915
	F=50.20		F=9.82	
	p<.0001		p<.0001	
	R ² =.63		R ² =.25	

* Controls: the presence (1) or absence (0) of another hospital in the area; the presence (1) or absence (0) of an inhalation therapy department; the presence (1) or absence (0) of physicians with research funds in the area of respiratory disease.

percent of the variance in the adoption of compatible innovations and for 25 percent of the variance in the adoption of non-compatible ones. Both regressions are highly significant.

As predicted, size has a significant, albeit small, impact upon the adoption of both types of innovations. This is consistent with the notion that organizations processing greater volume will be in a position to differentiate their techniques or services to articulate with variety in input material. Specialization and functional differentiation have significant impacts on the adoption of compatible innovations. This effect was expected to be attenuated in the case of noncompatible innovations; however, attenuation occurred only for specialization and this difference was not large. Functional differentiation affects the adoption frequency of both types of innovations.

Centralization and its interaction with size appear, as expected, to affect the adoption of compatible innovations; the same relationships do not appear in the case of noncompatible innovations. The coefficient describing the impact of centralization on the adoption of innovations compatible with the interests of specialists and department heads—those who make decisions in decentralized hospitals—is small but approaches statistical significance.⁷ It appears that decentraliza-

tion, as expected, affects the adoption of medical innovations; however, the data indicate that it does not lead to adoption of innovations which do not directly facilitate the work of lower-level decision-makers.

The interaction effect between centralization and size lends additional support to the self-interest perspective on adoption behavior. It was hypothesized that lower-level decision-makers would be most likely to allocate resources in their own interest when they had resource allocation discretion and when those responsible for the organization as a whole would incur significant costs were they to exercise their control prerogatives. These conditions obtain primarily in organizations which are simultaneously large and decentralized. The coefficient in Table 1 describing this interaction effect on the adoption of compatible innovations, .11, is consistent with this expectation. While it also is not large, it is statistically significant. Moreover, this interaction effect does not recur in the case of innovations which are not compatible with specialists' or department heads' interests.

Overall, the data provide considerable support for the theoretically derived model for the adoption of innovations compatible with the interests of lower-level personnel. They support most of the expectations regarding adoption of non-compatible innovations; however, the hypothesized relationship between functional differentiation and adoption of these types of innovations—expected to be zero

⁷ An analysis of covariance was conducted as an additional test for the main and interaction effects of centralization. This analysis confirmed both effects at or beyond the .05 level of significance (see Appendix).

or negative—clearly is not supported by the data. The deviations from expected relationships, particularly that between functional differentiation and the adoption of noncompatible innovations, suggest alterations in the theoretical perspective.

Structure, Innovation Type and Adoption Behavior: Discussion and Conclusions

Burns and Stalker (1961), Thompson (1969) and others have argued that there is an identifiable cluster of characteristics which determine an organization's proclivity for adopting new techniques. Others such as Wilson, (1966), Sapolsky (1967) and Hage and Dewar (1973) have argued that the values, interests and perspectives of those who allocate organizational resources play a significant part in the adoption process. The findings reported here suggest that attributes thought to characterize the generally innovative organization—specialization, differentiation and decentralization—do successfully predict to the frequency of adoption of innovations compatible with the interests or perspectives of lower-level decision-makers. Two of these attributes, however, failed to predict to the adoption of an innovation which is noncompatible. Specialization and centralization were significantly associated with only the adoption of compatible innovations; however, the difference between coefficients for specialization was small and must be taken as only suggestive. In addition, as expected, centralization appeared to interact with size to affect only the adoption of compatible innovations. This effect did not appear in the case of innovations which were not compatible. In short, different models appear to predict to the adoption of different types of innovations. The general model described by Burns and Stalker appears to be more applicable to some types of innovations than to others.

The model predicting to the adoption of noncompatible innovations was not completely supported by the data. It had been anticipated that those factors associated with adoption of compatible innovations, with the exception of size, would not be

associated, save perhaps negatively, with the adoption of noncompatible innovations. Hospitals which had a high degree of functional differentiation, however, were more, rather than less likely to have adopted noncompatible innovations. One possible explanation is that EDP, while less compatible than innovations used for diagnosis or treatment, is not incompatible with the interests of department heads, because these interests are as much administrative as medical. Department heads in hospitals, however, almost invariably are physicians, and their concerns tend to revolve around patient care rather than administration. The inconsistency, therefore, ought not to be dismissed as being due to a faulty appraisal of the relative compatibility of the two types of innovations studied. Rather, a theoretical adjustment appears to be called for.

A factor which had not been anticipated in the initial theoretical formulation involves the control requirements of the organization. Specifically, organizations which are highly functionally differentiated require greater coordination and integration among their constituent departments (Lawrence and Lorsch, 1967). Departments in hospitals, while relatively independent functionally, share—and often compete for—the same pool of resources. Optimal allocation of these resources, therefore, requires superordinate fiscal monitoring and control, and the importance of this requirement is likely to increase in proportion to the number of sharing or competing departments.

Competing department heads may be caught between a desire to realize their own interests and a need to constrain other department heads from obtaining more than their just due. As a collectivity, therefore, it may be in their own interest to encourage rather than discourage fiscal monitoring and control. This support would be forthcoming not because department heads tend to be concerned with administration per se, but because monitoring would decrease the opportunities available for other departments to acquire more than their share. This argument does not apply to specialization, since resource allocations tend to be made to departments rather than to individual

specialists. The relative compatibility of innovations under consideration, therefore, may be less relevant for highly differentiated organizations than for highly specialized ones. The impact of the interests of department heads on adoption behavior may be neutralized to the extent that these interests are in competition. More than this, the competitive situation may encourage department heads to support the adoption of innovations which would not directly facilitate their work were they not interdependent with others.

The empirical findings reported here can, within the limits mentioned earlier, be generalized to the population of U.S. hospitals. The theoretical perspective, however, promises to have more general applicability. The costs of control in many types of organizations are likely to increase with size and differentiation. The potential for divergence of interests or perspectives between specialists or department heads and top management—and among department heads themselves—is also present in industrial firms, government agencies, service organizations, etc. The impact of size conceived as input volume may also apply to organizations other than hospitals. These economies of scale, in fact, have

been documented in a wide variety of settings (e.g., Corwin, 1972; Mohr, 1969). The findings suggest that the adoption of innovations compatible with the interests of specialists and department heads will occur to the extent that the organizations are large, specialized, functionally differentiated and decentralized. Less compatible innovations, specifically those which facilitate coordination and control, are likely to be adopted by large and functionally differentiated organizations. Limits to the generalizability of these findings, of course, must be assessed through additional empirical research. Such efforts also ought to investigate adoption patterns for innovations which are clearly incompatible with the interests of top management or decision-makers located at lower levels in organizations.

THE ROLE OF INSTITUTIONALIZATION IN CULTURAL PERSISTENCE *

LYNNE G. ZUCKER

University of California, Los Angeles

American Sociological Review 1977, Vol. 42 (October):726-743

Traditional approaches to institutionalization do not provide an adequate explanation of cultural persistence. A much more adequate explanation can be found in the ethnomethodological approach to institutionalization, defining acts which are both objective (potentially repeatable by other actors without changing the meaning) and exterior (intersubjectively defined so that they can be viewed as part of external reality) as highly institutionalized. Three levels of institutionalization were created in the autokinetic situation to permit examination of the effects of institutionalization on three aspects of cultural persistence: generational uniformity of cultural understandings, maintenance of these understandings, and resistance of these understandings to change. Three separate experiments were conducted to examine these aspects of cultural persistence. Strong support was found for the predictions that the greater the degree of institutionalization, the greater the generational uniformity, maintenance, and resistance to change of cultural understandings. Implications of these findings for earlier approaches to institutionalization are discussed.

"The only idea common to all usages of the term 'institution' is that of some sort of establishment of relative permanence of a distinctly social sort" (Hughes, 1936:180). Specific explanations of cultural persistence have been varied and, frequently, institutionalization and persistence have not been clearly separated conceptually. This paper will show that a more fully developed conception of institutionalization derived in part from the ethnomethodological approach can be used to make clearer predictions about cultural persistence. Much of the confusion of earlier discussions of institutionalization centers on the use of intervening mechanisms to explain persistence. It is argued here that internalization, self-reward, or other intervening processes need not be present to ensure cultural persistence because social knowledge once institutionalized exists as a fact, as part of objective reality, and can be

transmitted directly on that basis. For highly institutionalized acts, it is sufficient for one person simply to tell another that this is how things are done. Each individual is motivated to comply because otherwise his actions and those of others in the system cannot be understood (Schutz, 1962; Berger and Luckmann, 1967); the fundamental process is one in which the moral becomes factual.¹ Yet institutionalization is not simply present or absent; unlike many of the earlier approaches, institutionalization is defined here as a variable, with different degrees of institutionalization altering the cultural persistence which can be expected.

The research reported here investigates

* I wish to thank Morris Zelditch, Jr., John W. Meyer and Anne M. McMahon for their assistance throughout the research reported here. In addition, I would like to thank the following people for extensive comments on an earlier version of this paper which the author presented at the West Coast Conference on Small Group Research in Victoria, Canada, April, 1975: Phillip Bonacich, Mel Pollner and Ralph H. Turner.

¹ Ethnomethodologists deal both with emergent culture, facing the problem of creating new culture, and with existing culture, facing the problem of cultural persistence. It is this second thread of ethnomethodology which is selected for further examination in this paper. When emergent culture is the focus, then the problem of establishing facticity becomes the central problem. It is here that the moral character of social facts becomes the central concern (Garfinkel, 1967). When the social facts are not well established, their transmission is problematic and may well depend on an obligatory, moral response to a specific situation. However, when social facts are well established, the moral character becomes less significant than the cognitive. It is this situation that is examined further here.

the effect of different degrees of institutionalization in constructed realities on cultural persistence in three distinct experiments, each one focusing on a different aspect of persistence. First, for cultural persistence, transmission from one generation to the next must occur, with the degree of generational uniformity directly related to the degree of institutionalization (Transmission Experiment). Second, once transmission has taken place, maintenance of the culture must occur, with the degree of maintenance directly related to the degree of institutionalization (Maintenance Experiment). Third, once maintenance has occurred, cultural persistence depends on the resistance to attempts to change, with the degree of resistance directly related to the degree of institutionalization (Resistance to Change Experiment).

Traditional Explanations of Cultural Persistence

Two traditional explanations of cultural persistence have received the most attention in the literature: the subsystem approach and the normative framework approach. The subsystem approach focuses on specific clusters or sectors, such as Family, Economy or Polity. Institutional subsystems, then, are separate spheres of activity, each with distinctive clusters of norms and each forming a distinct part of a typology of institutions. While the specific typology used varies widely (see Storer, 1973; Bierstedt et al., 1964; Merton et al., 1959), explanations for persistence rest on functional necessity (Angell, 1936) or on self-interested desire for rewards (Blake and Davis, 1964; Parsons, 1939; 1940; Sumner, 1906). However, both explanations have received strong criticism. First, it is difficult to determine functional necessity independently of persistence; in fact, persistence often is used as an indicator of functional necessity. Second, it has been found that some actions in institutions appear to require sanctions while others do not, so that direct social control cannot fully explain persistence.

The other major traditional approach focuses on the normative framework of institutions which persists because the

norms are shared. No external motivation for conformity is necessary because norms which are central to institutions become internalized. The actor is internally motivated to do what he has to do (Parsons, 1951; Berger and Luckmann, 1967). However, the normative framework approach provides no criteria for separating processes which are institutionalized from those which are not. There is no independent measure of which norms are most important in a social system—it is only after a norm is internalized that it can be identified as institutionalized. Further, there are no explicit criteria for determining whether or not an act is internalized. Certainly, actions performed without direct social control will not necessarily be considered internalized. Yet it is not clear how to distinguish internalization of acts on any other basis.

When explaining persistence, both traditional approaches to institutions focus on the actor's compliance with the action prescribed by the institution. Recognition of functional necessity, self-interest or internalization are thought to motivate the actor to comply. The actor plays no independent role in maintaining these institutions, rather they serve to constrain his behavior. The social structure (macro-level) determines the behavior of individuals and small groups (micro-level) and exists independently of them. While the limitations of traditional approaches to institutionalization have been stressed, they are appropriate to deal with some aspects of institutionalization and the transmission of some kinds of meaning. In fact, they may provide good explanations when institutionalization is low.

The Ethnomethodological Approach to Institutionalization

A relatively recent approach, the ethnomethodological approach, provides a strikingly different view of the role played by institutions in cultural persistence, dealing explicitly with highly institutionalized action. Reality, while socially constructed, is "*experienced* as an intersubjective world known-or-knowable-in-common-with others," which exists historically prior to the actors and fur-

nishes "the resistant 'objective structures' " which constrain action (Zimmerman and Pollner, 1970:37). To arrive at shared definitions of reality, individual actors transmit an exterior and objective reality; while at the same time this reality, through its qualities of exteriority and objectivity, defines what is real for these same actors. Macro-level and micro-level are inextricably intertwined. Each actor fundamentally perceives and describes social reality by enacting it and, in this way, transmits it to the other actors in the social system (Berger, 1968). Generational transmission provides the clearest example of this process. The young are enculturated by the previous generation, while they in turn enculturate the next generation. The grandparents don't have to be present to ensure adequate transmission of this general cultural meaning. Each generation simply believes it is describing objective reality.

Hence, institutionalization is both a process and a property variable. It is the process by which individual actors transmit what is socially defined as real and, at the same time, at any point in the process the meaning of an act can be defined as more or less a taken-for-granted part of this social reality. Institutionalized acts, then, must be perceived as both *objective* and *exterior*. Acts are *objective* when they are potentially repeatable by other actors without changing the common understanding of the act, while acts are *exterior* when subjective understanding of acts is reconstructed as intersubjective understanding so that the acts are seen as part of the external world (see Berger and Luckmann, 1967, on "reification" and "objectivation").

Objectification and exteriority often covary, with an increase in one causally producing an increase in the other. Depending on the specific relationship between these two variables, the degree of institutionalization can vary from high to low. Hence, acts may vary in the degree to which they are institutionalized. When acts have ready-made accounts (Garfinkel, 1967), they are institutionalized; that is both objective and exterior. Ready-made accounts won't exist for acts unique to a single actor nor for acts where inter-

subjective knowledge is low. While these accounts are socially created, they function as objective rules because their social origin is ignored (Schutz, 1962). At the same time, ready-made accounts define the *possible*—institutionalization makes clear what is rational in an objective sense. Other acts are meaningless, even unthinkable (Meyer, 1971). Thus, direct social control—whether through incentives or negative sanctions—is not necessary. In fact, applying sanctions to institutionalized acts may have the effect of de-institutionalizing them. They may seem less objective and impersonal, less factual—and the very act of sanctioning may indicate that there are other possible, attractive alternatives.

But acts are not simply either institutionalized or not institutionalized. The meaning of an act may be perceived as more or less exterior and objective, depending on the situation in which the act is performed and/or depending on the position and role occupied by the actor. For example, acts which are dependent on a particular unique actor are low on institutionalization as in personal influence.² In contrast, acts which are performed by an actor occupying a specified position or role are high on institutionalization.

Settings can vary in the degree to which acts in them are institutionalized. By being embedded in broader contexts where acts are viewed as institutionalized, acts in specific situations come to be viewed as institutionalized. Indicating that a situation is structured like situations in an organization makes the actors assume that the actions required of them by other actors in that situation will be those typical of a more formal and less personal interaction. This assumption leads the actors to believe that acts will be more regularized and that the interaction will be more definitely patterned than if the situa-

² Personal influence is used throughout this paper to mean direct influence between actors who perceive each other as equals. Influence between actors who are seen as occupying differentiated roles or who are seen as interacting in a specialized setting governed by consensual rules is *not* considered to be personal influence.

tion were not embedded in an organizational context.

Any act performed by the occupant of an office is seen as highly objectified and exterior. When an actor occupies an office, acts are seen as nonpersonal and as continuing over time, across different actors (Hughes, 1937). In addition, an office increases intersubjective knowledge of appropriate action (Weber, 1947; Berger and Luckmann, 1967). Both the position and role of the occupant establish conditions which maximize treating any act as an accurate reflection of a "fact of life." Thus, acts performed by occupants of an office are by definition institutionalized, though the degree of institutionalization may vary.

In contrast to office, personal influence is dependent on the particular unique actor. There is no rationale under which such an actor can be replaced without changing many of the expectations for behavior. When an actor exercising personal influence leaves the situation, the next actor cannot be classified as having the same quality or qualities. The effect of unique personal influence depends solely on the characteristics of the particular people interacting. In no way is legitimacy derived from other actors or contexts. Each actor is taken as unique and each one influences others independently on that basis. Acts performed by actors exercising personal influence are low in objectification and exteriority, hence low in institutionalization.

Implications of the Ethnomethodological Approach to Institutionalization for Cultural Persistence

As described above, three aspects of cultural persistence are directly affected by institutionalization: transmission, maintenance and resistance to change. Institutionalization is thought to increase all three.

Transmission is defined as the process by which cultural understandings are communicated to a succession of actors. Cultural understandings may be transmitted either in a branching manner, in which each successive actor communicates the meaning to multiple actors, or in a purely

sequential one, producing a chain of actors each of whom communicates the meaning only to the next actor on the chain. In any case, whether transmission occurs within a single "generation" or between "generations," it proceeds from actor to actor independent of any of the earlier transmitting actors.

It is argued here that transmission of acts high on institutionalization is not problematic. The actor doing the transmitting simply will communicate them as objective fact, and the actor receiving them will treat them as an accurate rendition of objective fact. However, depending on the degree of institutionalization of acts, transmission of them will vary. Some transmission will occur with personal influence (as shown in Jacobs and Campbell, 1961); but since acts performed by actors exercising personal influence are low on exteriority and objectification (unique to the particular actor and not transferable to succeeding actors), personal influence will not have as great an effect on transmission as institutionalized context or office. That is, while some transmission occurs with personal influence, increasing objectification and exteriority will increase transmission.

Continuity of the transmission process will also increase institutionalization. The more the history of the transmission process is known, the greater the degree of continuity the actors assume. The history of transmission provides a basis for assuming that the meaning of the act is part of the intersubjective common-sense world. As continuity increases, the acts are increasingly objectified and made exterior to the particular interaction. The act is clearly repeatable, not tied to a unique actor or situation. The basic assumption, then, is that continuity causally produces objectification and exteriority.

Turning now to maintenance, one major assumption is that transmission of acts high on institutionalization is sufficient for maintenance of these same acts. While there are a large number of experimental findings illustrating the central role that direct social control plays in maintaining or modifying behavior, in these experiments the acts to be maintained are generally low on institutionalization and,

further, other methods of modifying or maintaining behavior are not examined. In this theoretical approach, it is argued that the degree of institutionalization radically affects the role and impact of direct social control. For acts low on institutionalization, direct social control (or other intervening mechanisms, such as internalization) is necessary, while for acts high on institutionalization, all that is required is transmission. The institutionalization process simply defines social reality and will be transmitted and maintained as fact.

The third aspect of cultural persistence which should vary with the degree of institutionalization is resistance to change. Acts high on institutionalization will be resistant to attempts to change them through personal influence because they are seen as external facts, imposed on the setting and, at the same time, defining it. Acts performed by actors exercising personal influence, on the other hand, are seen as highly dependent, both on the particular actor and on the particular situation in which the influence attempt is made. Thus, once an act high on institutionalization is transmitted, attempts to change it through personal influence will not be successful and, in fact, may result in a redefinition of the actor rather than the act.

Each one of these aspects of cultural persistence was examined in a separate laboratory experiment in which institutionalization could be varied.

General Experimental Design

The research problem requires a situation in which institutionalization of acts can vary from high to low. While the degree of institutionalization can vary in both ambiguous and unambiguous settings, it can be varied more readily in ambiguous settings (Cicourel, 1964:ch. 7). Hence, this initial experimental investigation is limited to the less problematic ambiguous setting. In addition, it is necessary that all actors in the situation be committed to obtaining an appropriate understanding of the situation (Garfinkel, 1967:ch. 1), though not necessarily committed to the task itself. Further, the task must be one which does not have preexist-

ing relevance to organizational settings, to minimize the possibility of normative, obligatory responses. The more tenuous and unbelievable the connection between the experimental setting and organizational settings, the more likely that differences can be attributed to a cognitive understanding of the "facts of life" rather than obligatory conformity. Finally, the setting must be sufficiently flexible to permit examination of transmission of a preestablished set of norms to actors new to the situation.

A setting which is ambiguous, generates commitment to obtaining a common understanding of the situation, does not have preexisting relevance to organizations, and can be flexibly designed is the autokinetic situation (Sherif, 1935).³ The autokinetic effect is a visual illusion—a stationary pinpoint of light presented in a totally dark room appears to move, smoothly or erratically. In his early studies, Sherif (1935) found that subjects alone developed a judgment standard for the apparent movement and that the particular standard was peculiar to the individual. Over time (three sessions in one week), this standard remained highly stable. He also found that in group situations individuals did not form their own judgment standards but, rather, that the group as a whole established a standard peculiar to that group.⁴

By varying Sherif's basic design, Jacobs and Campbell (1961) developed a transmission situation consisting of a series of stages, referred to as generations, each of

³ There is much support in articles published since Sherif's original study for the claim that the underlying effect is highly variable, including studies of the physiological basis of the effect (Marshall, 1966; Gregory and Zangweil, 1963; Farrow et al., 1965). The effect is so unstructured that it frequently has been proposed as a projective technique (Cornwell, 1966; Rechtschaffen and Mednick, 1955).

⁴ As demonstrated in an earlier study (Alexander et al., 1970), expectations that the light movement will be patterned and stable account for judgmental convergence. When subjects' expectations are altered, either through instructions explaining the autokinetic illusion or through overhearing a confederate give divergent judgments of a light they could not see, it was found that subjects' judgments did not converge. However, Sherif's basic instructions, used in the experiments reported in this paper, lead subjects to exhibit judgmental convergence.

which contains two people, one who has judged the previous set of light exposures and one who is new to the situation. In the first generation, the person identified as having just participated in a preceding generation is a confederate who judges the light as moving considerably farther than subjects do who respond alone to the light (the "control" group). The confederate represents an existing enculturated definer of the situation, transmitting a distance judgment standard to the first subject. In the next generation, the confederate leaves the experiment, a new subject is brought in, and the enculturated subject transmits to the new subject. The same procedure is followed in succeeding generations.

Jacobs and Campbell (1961:342-3) were concerned with "manipulating cultural strength" by varying the number of "culture-bearing" confederates and by varying the number of naive subjects. For each experimental condition, generations were continued until the judgments were approximately equal to those in the control condition (judging light movement alone). While Jacobs and Campbell had anticipated producing strong cultures, their findings did not support this prediction. After the last generation with the confederate, the arbitrary norm was transmitted in some degree only to the fourth or fifth generation. Little difference was found between conditions with different numbers of confederates.

In the research reported here, it was expected that varying institutionalization would produce more striking differences. Instructions were used to create three levels of institutionalization. The higher the level of institutionalization, the higher

the transmission maintenance and resistance to change of cultural understanding expected. Each of the aspects was examined in a separate experiment. Figure 1 presents a summary of the overall design for the three experiments.

TRANSMISSION EXPERIMENT

The Transmission Experiment tests the proposition that the greater the degree of institutionalization, the greater the generational uniformity of cultural understandings. It was predicted that the generational uniformity of cultural understandings would be, at least with personal influence, highest with organizational context and office and intermediate with organizational context alone.

Subjects

A total of 180 female subjects were used, with 45 subjects in each of the three experimental conditions and 45 subjects in the control condition. Three generations were used, with fifteen replications in each condition.

Apparatus and Procedure

The experiment took place in a completely darkened room to facilitate perception of the autokinetic phenomenon. To provide a constant exposure time, the light was operated by a timer, coupled with a motor, as in the Jacobs and Campbell study. Each naive subject was read the instructions for the appropriate condition prior to entering the experimental room. In the *control condition*, the instructions focused on the task, with no

TRANSMISSION

Order of Response	1st Generation	2nd Generation	3rd Generation	MAIN-TENANCE	RESIS-TANCE TO CHANGE ^a
First	Confederate	Subject 1	Subject 2	Subject 3 (Alone)	Confederate
Second	Subject 1	Subject 2	Subject 3		Subject 3

^a Maintenance and Resistance to Change Experiments are conducted when Subject 3 returns one week after the Transmission Experiment.

Figure 1. Experimental Design Summary

information about social characteristics or understandings:

This is a study of visual perception. It requires judgments made with limited information. In a few minutes, you will be brought into the next room. In this room is an apparatus that will project a small light. After the light appears, it begins to move. Let me explain what you will be doing. You must judge the distance that the light moves from the time that it appears until it is turned off. You will repeat this procedure a number of times. Each time the light is shown, you will be asked to judge the distance the light moved in inches along a straight line connecting the starting point and the ending point. After each time the light is turned off, you will be asked to say how far the light moved.

Try to make your judgments as accurate as possible.

Please fill out the card on the desk. As you will notice, it has been numbered. To assure anonymity in this study, each participant is assigned a number and all names are removed from any records.

The *personal influence condition* closely followed the Jacobs and Campbell (1961) instructions and included the full description of the task as in the control condition instructions:

This study involves problem solving in groups. You will be participating with another person. There are already two people at work in the next room. . . .

To simplify the recording procedure, the person who is already in the room will be asked for her judgment first. At this point, you will be asked for your judgment second. After a while, the other person will leave, you will take her place, and a new person will be brought in. Then you will be asked for your judgment first. . . .

The *organizational context condition* instructions incorporated organizational context and continuity (modified from Weick and Gilfillan, 1971), otherwise retaining the same wording as the personal influence condition:

This study involves problem solving in model organizations. You will be par-

ticipating with another organizational member. Your two-member organization is meant to be a small-scale model of much larger organizations, and it has many of the same characteristics they do.

Most large organizations continue even though individual members, or even whole divisions, may be replaced, due to changing jobs, retirement, reorganization, etc. The model organization in which you will participate also will have this feature: members who have been in it for a while will drop out, and new members will join, but the job will go on. Thus, performance of any single member may not be important to the organization as long as the job continues to be done.

There is already a two-member organization operating in the next room. In a few minutes, one of the members will leave, and you will be brought in. After you have worked together with the other member for some time, you will take her place. Then a new member will be brought in as a replacement, becoming part of the organization. . . .

The *office condition* instructions were built directly on the organizational context instructions, adding an office:

Large organizations also place members in different positions, often according to the amount of time spent in the organization. The model organization in which you will participate also has this feature—the member who has spent the most time in the organization will be the Light Operator. Thus, the member already in the next room, having already participated in the organization, will be the Light Operator. When she leaves, you will become the Light Operator.

As you may already have guessed, the group member labeled Light Operator will be responsible for turning the light on after each member gives her judgment on the previous movement. The Light Operator in each case must depress a button to activate the light. From then on, the timing and motion of the light is controlled automatically until the next trial.

To simplify the recording procedure,

the Light Operator will be asked for her judgment first. She will be called Member 1. At this point, you will be asked for your judgment second. You will be called Member 2. After a while, the Light Operator will leave, you will take her place as Light Operator, and a new member will be brought in. Then you will be asked for your judgment first, being called Member 1. . . .

In each case, the subject was asked to fill out a numbered card designed to enhance the continuity manipulation in the instructions. In the personal influence condition, low on continuity, the number assigned to each subject was 3; in the organizational context and office conditions, each subject was assigned number 103; while in the control condition, number 21 was assigned to each subject, representing neither low nor high continuity.

After the subjects were led into the experimental room, they were seated side by side eight feet from the light box. All subjects were blindfolded before entering the room and between generations so that no visual contact with other subjects was made. The experimenter communicated with the subjects using a microphone system and prompted responses with a name or number (depending on condition). In the personal influence and organizational context conditions, the experimenter controlled the timer and prompted responses by using the subject's first name. In the office condition, however, the subject who had been in the room longest controlled the timer placed next to her in the second set of thirty trials. The subject simply depressed a button which activated the light for a fixed period of time. Responses were prompted by "Member 1" and "Member 2" in the first trial, then simply "1" and "2."

The light was presented and the subjects' responses (judgments of the light movement in inches) recorded for a block of thirty trials. After each block of trials, the senior member of the group was taken out, the other member moved to the right seat, and a new member was brought in. In the first generation, the experienced member was a confederate who had been

instructed how to respond. The confederate was instructed to make judgments with a mean of 12 and a range of 9 to 15 (from Sherif, 1967).

After each generation, the subject taken from the room was conducted to an interview room. If she was the last subject in the Transmission Experiment (each group consisted of three generations), she was not interviewed but scheduled to return again one week later.

Results

Control condition. The control condition was designed to provide a baseline for all experimental data collected, with a single subject responding alone to the light for 90 trials. This makes it clear what degree of change occurred when a higher initial standard of judgment was provided by a confederate in the experimental conditions. It was found that the mean response of the 45 subjects in the control condition was highly consistent across the three blocks of 30 trials (4.37, 3.95, 3.95 inches). Thus, unlike results reported by Sherif (1935) and Jacobs and Campbell (1961) which showed a steady and significant decline in judgments, the mean judgments of the 45 control subjects in this experiment did not show a significant decline. Hence, the baseline response can be defined as the average of all judgments (90 trials): 4.16 inches.

Experimental conditions. The predictions that transmission (and, hence, generational uniformity) would be greater in the organizational context condition than in the personal influence condition, and greater in the office condition than in the organizational context condition are examined in two main ways. First, the response levels of successive naive subjects are used to define a transmission coefficient, permitting prediction of response levels of later generations. Second, mean response levels of naive subjects over the three generations are compared to test the predicted ordering of the experimental conditions.

Turning first to the discussion of the transmission coefficient, the use of mean response levels of successive naive (new)

Table 1. Transmission Coefficients Defining Rate of Decline of Response Level for Each Experimental Condition

Transmission Coefficients	Institutionalization		
	Personal Influence	Organizational Context	Office
T ₁ (First to Second Generations)	.49	.87	.92
T ₂ (Second to Third Generations)	.37	.89	.97
T (Average Coefficient)	.43	.88	.94

subjects to predict response levels of later generations was suggested by Jacobs and Campbell's (1961) data. Although not noticed by them, in their data for all four conditions the relative rate of decline in response level toward the baseline remains essentially constant between generations in the same conditions. This is most clearly illustrated in their Figure 2 (Jacobs and Campbell, 1961:345): with a baseline of 3.8 inches, the naive subject made mean judgments (in 30 trials) of 12.4, 9.3, 7.1 and 5.8 inches. Examining the ratio of elevations above the baseline in successive generations, it can be seen that it remains essentially constant:

$$\frac{9.3-3.8}{12.4-3.8} = .64,$$

$$\frac{7.1-3.8}{9.3-3.8} = .60,$$

$$\frac{5.8-3.8}{7.1-3.8} = .61.$$

In designing the experiment reported here, it was assumed that this decline, so characteristic of the Jacobs and Campbell data and also clear in Sherif (1967:264-8), is a general characteristic of generational transmission in the autokinetic situation. The essentially constant geometric decline toward the baseline permits prediction of the response levels of later generations, so that it is not necessary to collect data on all generations.

Before turning to the specific results in this experiment, the measure of relative rate of decline in response levels should be more generally expressed as a transmission coefficient. This measure of transmission is based on a comparison of

the response levels of the naive (new) subjects in each generation, where response level is defined as the mean of a subject's judgments over thirty trials. The transmission coefficient then can be defined as the ratio of elevations above the baseline of successive naive subjects:

$$T_i = \frac{\bar{S}_{i+1} - B}{\bar{S}_i - B} \quad (i = 1, 2)$$

where \bar{S}_i is the average response of the i th subjects in the naive position and B is the baseline response. One desirable property of the transmission coefficient defined in this manner is that it permits prediction of the generation at which the response level will approximate the baseline allowing a more direct reflection of experimental findings. Since actual experimental data cannot be expected to be completely constant, an average transmission coefficient defined as

$$T = \frac{T_1 + T_2}{2},$$

will be used.

Table 1 presents the average transmission coefficients (T) for the three generations in this experiment.⁵ The transmission coefficients for each pair of generations (T_1 and T_2) in each condition were essentially constant. There was a greater difference between the coefficients in the

⁵ While it is technically possible to use two generations—one ratio of elevation above the baseline—three generations were used to test the assumption that the decline was also constant in the experiment described here.

personal influence condition than between those in the other two conditions, possibly because the response level in the third generation closely approximates the baseline response.

Figure 2 presents the extrapolated response levels based on the average transmission coefficient, T , for each experimental condition, as well as the actual experimental data on which the coefficients were based. The predicted differences between the three conditions are clearly found. In the personal influence condition, the extrapolated response level approximates the baseline response in the 7th generation, while in the organizational context condition, the extrapolated response level doesn't approximate the baseline response until the 29th generation. Even in the 38th generation, in the office condition, the extrapolated response level doesn't yet approximate the baseline response.

Now direct comparisons between the mean response levels of naive subjects will be made to permit significance tests of

the predicted ordering of the experimental conditions. Table 2 presents these mean response levels by condition. The predicted ordering for the magnitude of response level was obtained:

Personal influence <
organizational context < office.

In the personal influence condition, the mean response level of naive subjects declined rapidly so that it was only slightly above the baseline by the third generation (4.58 compared to 4.16 for the baseline response).

In order to evaluate the magnitude of the differences in response level by condition, analysis of variance was used. Because comparisons between different levels of institutionalization involve differences between generations as well as differences associated with institutionalization itself, customary two-way analysis of variance is not appropriate. Instead, analysis of variance for the special case of the two-factor experiment with repeated measures on one factor is used in Table 3

Figure 2. Extrapolated Response Levels Based on Transmission Coefficients Determined by the First Three Generations in Each Condition

Table 2. Mean Response Level of Naive Subjects over Three Generations in the Transmission Experiment

Generation	Institutionalization		
	Personal Influence	Organizational Context	Office
First	6.53	9.44	10.51
Second	5.31	8.77	10.00
Third	4.58	8.25	9.79

(Winer, 1962:298-318). The data provide clear support for the statistical significance of the main effects due to institutionalization.⁶

To recapitulate briefly, the Transmission Experiment tests the proposition that if institutionalization is increased, then generational uniformity of cultural understandings will be greater. From the preceding analysis of the data, it is clear that the effects of institutionalization occurred as predicted. Further interpretation of results will be deferred until all three experiments have been described. Before turning to the Maintenance Experiment, results bearing on the effectiveness of the experimental manipulations will be reported.

Effectiveness of the Experimental Manipulations

As described earlier, the instructions read at the beginning of the experiment were designed to manipulate the degree of institutionalization. Since this is the only

manipulation of the independent variables for all three experiments reported here, it is crucial to assess its effectiveness. Therefore, rather than attempt to assess this directly, a number of other variables which were expected to vary directly with the degree of institutionalization were chosen to validate the manipulation. Specifically, it was predicted that increasing institutionalization should increase the subjects' subjective certainty of the accuracy of their judgments, subjects' reported ease in estimating light movement, and subjects' reported expectations that their answers should be the same as those of the experienced subject (the transmitter of cultural understandings). In addition, it was predicted that the occupant of the office position would be seen as less personal; the highly institutionalized position should increase the role distance and significantly affect perception of attributes of the occupant of that position.

Parts of the postexperimental questionnaire and the adjective list (given before the questionnaire) were designed to determine whether these additional dependent variables designed to measure validity did indeed vary with the degree of institutionalization. Turning first to the questionnaire results, subjects were asked three questions reflecting perception of

⁶ The mechanisms underlying differential transmissions were also explored, comparing response levels of the same subjects when in the naive and experienced positions. Results available from the author by request.

Table 3. Analysis of Variance Test on the Mean Response Level of Naive Subjects

Source of Variance	Sum of Squares	df	Mean Square	F	Significance Level*
Between Groups					
A (Condition)	514.75	2	257.37	74.83	p<.001
Subjects within Groups	144.45	42	3.44		
Within Groups					
B (Generation)	37.96	2	18.98	9.42	p<.001
B x Subjects within Groups	169.30	84	2.02		

* Under the more conservative, negatively biased test.

institutionalization. First, subjects were asked: "How certain were you of the accuracy of your judgments?" They were shown a separate card on which was drawn a seven-point scale, where one represented "Certain" and seven indicated "Uncertain." Certainty was predicted to increase with increasing institutionalization, because it reflected certainty in the accuracy of the group standard, not individual judgment. Subjects in the more institutionalized conditions were predicted both to be more certain of their judgment and to change more toward the confederate's judgments from the baseline response in the Transmission Experiment, a prediction contrary to the assumption made in many psychological studies where certainty is thought to increase resistance to change (Boomer, 1959).

Second, subjects were asked about ease of judgment: "Was it difficult to estimate the distance the light moved?" It was predicted that the more institutionalized and, therefore, certain about accuracy, the easier estimating light movement should be. In the absence of objective criteria for determining difficulty of judgment, assessment of difficulty would rest on a trial-by-trial examination of difficulty in reaching a decision. Where certainty in the accuracy of group standards is high (in the more institutionalized conditions), decisions should be less difficult. Hence, in this case, certainty determines difficulty rather than difficulty determining certainty as most studies assume (Coleman et al., 1958; Kretch and Crutchfield, 1962; Freedman et al., 1974).

The third question asked in the postses-

sion interview which reflected perception of institutionalization was: "Did you feel that your answers *should* be the same as the other person in the first set of judgments?" It was predicted that the greater the degree of institutionalization, the more frequently the subject would report that her responses should be the same as the other person in the "experienced" or transmitter position. The more institutionalized, the more subjects should feel normatively constrained to transmit the confederate's standard.

The responses on these three questions on the postexperiment questionnaire are summarized in Table 4. Each of the three sets of findings is in the predicted direction. Subjects were much less certain of their accuracy in the personal influence condition than in either of the more institutionalized conditions. While subjects in the organizational context condition were less certain of their accuracy than subjects in the office condition, the difference was not striking. Turning now to the responses to the question, "Was it difficult to estimate the distance the light moves," as predicted, fewer subjects in the office condition reported difficulty than in the organizational context condition. Nearly all subjects in the personal influence condition reported difficulty. Finally, over half of the subjects in the personal influence condition did *not* feel normatively constrained to give the same response as the confederate, compared to less than a quarter of the subjects in the organizational context condition. Only seven percent in the office condition did not feel normatively constrained.

Table 4. Questionnaire Responses by Experimental Condition ^a

Question	Institutionalization		
	Personal Influence	Organizational Context	Office
Mean Certainty Score ^b	5.35	3.62	3.22
Number Reporting Judgment Difficulty	41	26	16
Number <i>Not</i> Feeling ^c Answer Should Be Same As Experienced Subjects	28	11	3

^a N in each condition is 45.

^b The smaller the number, the more certain of own judgment accuracy. Scale is from one to seven.

^c Question reversed so that all predicted magnitudes in the table would be in the same direction.

Table 5. Differences in Response Level between the Last 30 Trials in the Transmission Experiment and the 30 Trials in the Maintenance Experiment

Difference between Transmission and Maintenance Experiments	Institutionalization		
	Personal Influence	Organizational Context	Office
Third Subject	.78	-.08	-.47

Turning now to the adjective checklist, it was designed primarily as a check on the office manipulation. Six adjective-pairs were chosen to indicate role distance and the nonpersonal nature of office. Comparing the person occupying the experienced position in the office condition with the person occupying that position in the personal influence condition for each of these adjective pairs, the subjects in the office were characterized more frequently as decisive, cold, unsociable, dominant, methodical and unemotional. Each of these differences, except the unsociable-sociable comparison, is significant by the t-test.⁷

MAINTENANCE EXPERIMENT

The Maintenance Experiment was designed to test the proposition that the greater the degree of institutionalization, the greater the extent of maintenance of cultural understandings without direct control. The subjects in the personal influence condition were expected to maintain the Transmission Experiment response level least well, with subjects in the office condition maintaining it to the highest degree and subjects in the organizational context condition intermediate.

Subjects

The third subject from each group in the Transmission Experiment returned one week later, hence the total subjects available for the Maintenance Experiment were 15 subjects per condition, for a total of 45 subjects.

Apparatus and Procedure

The same apparatus was used as in the Transmission Experiment as well as the same procedures, with the following exceptions: (1) It is not a transmission situation, hence the generational design was not used. (2) The subject responded alone for the thirty trials.

The subject was read instructions (the same for all subjects in the Maintenance Experiment, regardless of experimental condition) identical to those used in the *control condition*, except that they were prefaced with "As you will remember. . . ." The subject was told that the other person scheduled for the same time had not arrived yet and in order to refresh her memory about the task, she would judge the light movement alone until the other person arrived.

Results

Analysis of the results is based on a comparison between the same subject's responses in the last thirty trials in the Transmission Experiment and the thirty trials in the Maintenance Experiment. The mean differences in response levels between these two phases are presented in Table 5. The ordering of magnitude of the differences is as predicted:

Personal influence <
organizational context < office.

However, it was not predicted that the means would actually increase very slightly in the organizational context and office conditions.⁸

⁸ Absolute differences are used because any changes, even an increase in response level, are due to the subject's perception of the common understanding in the situation. The slight increase in

⁷ Tables available from the author by request.

Table 6. Analysis of Variance Test on the Difference in Response Level of the Same Subject in the Transmission and Maintenance Experiments

Source of Variance	Sum of Squares	df	Mean Square	F	Significance Level
Between Groups	12.35	2	6.17	5.27	$p < .01$
Within Groups	49.18	42	1.17		

Analysis of variance was used to examine the difference between response levels of the same subject in the transmission phase and the maintenance phase. These results are presented in Table 6. The data provide clear support for the statistical significance of the main effects on maintenance of cultural understandings due to institutionalization.

Resistance to Change Experiment

The Resistance to Change Experiment was designed to test the proposition that the greater the degree of institutionalization, the greater the resistance to change in cultural understandings through personal influence. A change in the definition of the situation is attempted.

After the trials alone (Maintenance Experiment), a confederate was brought in, identified as the late other subject. The confederate, responding first, attempted to establish a lower-than-baseline response level, permitting measurement of resistance to change. The confederate's judgment had a mean of approximately 1.5 and a range of $\frac{1}{2}$ to $2\frac{1}{2}$ inches. It was predicted that judgments in the personal influence condition would be less resistant to change than judgments in the organizational context condition, and that judgments in the organizational context condition would be less resistant to

change than judgments in the office condition.

Subjects

The Resistance to Change Experiment was a continuation of the Maintenance Experiment and, therefore, had the same subjects.

Apparatus and Procedure

Again, the same apparatus was used. The same procedure was used as in the Maintenance Experiment except that a confederate was brought in. Thirty trials each were given, the confederate responding first, since "she didn't have the refresher session." No other instructions were given.

Results

A comparison between the thirty trials in the Maintenance Experiment and the thirty trials for the same subject in the Resistance to Change Experiment provided the basis for analysis of the results. The mean difference in response levels between the two experiments are presented in Table 7. The ordering is as predicted, with the personal influence condition having the greatest change, the organizational context condition less change and the office condition the least change.

Analysis of variance was used to examine the differences between response levels of the same subject in the Maintenance Experiment and the Resistance to Change Experiment. Table 8 presents the results. The data provide clear support for the predicted effects of institutionalization on resistance to change. Thus, the analysis of results in the Resistance to Change Experiment uniformly support the predictions made.

means in the two more institutionalized conditions is probably due to a "ceiling effect." Responses overall were maintained to a high degree. When developing the design used here, it was assumed that judgment standards artificially established through a confederate plus a one-week time span would be less well maintained than earlier studies found. Such was not the case. In future experiments, the problem of near-perfect maintenance may be avoided by using a more structured, less ambiguous setting in which an artificial definition of the situation would be less well maintained.

Table 7. Difference in Response Level between the Maintenance and Resistance to Change Experiments

Difference between Maintenance and Resistance to Change Experiments	Institutionalization		
	Personal Influence	Organizational Context	Office
Third Subject	1.59	1.03	.05

CONCLUSIONS AND IMPLICATIONS

The predictions derived from an ethnomethodological approach to institutionalization receive strong support in the results of the three experiments reported here. Each specific finding has a number of implications for research on institutionalization and poses significant issues which have not been sufficiently addressed in other, more traditional, theoretical approaches to the problem of cultural persistence.

Transmission of Cultural Understandings

Given that cultural understandings are socially constructed, the problem is to explain why some are so permanent and universal while others are unique to person, place or time. The Transmission Experiment was designed to test specific ideas about the mechanisms underlying generational uniformity, identifying the degree of institutionalization (both objective and exterior) as a determinant of this uniformity.

A number of alternative explanations of the results could be made, but none are as convincing as the ethnomethodological explanation on which the experiment was based. Specifically, creating an organizational context may implicitly lead the naive subjects to believe that they are expected by the experimenter to conform to the "more experienced" subject. On the basis of the experimental procedures alone, this seems unlikely, since in every condition naive subjects know at the out-

set that they will occupy the other position. Further, the task itself is unrelated to organizational settings. The strongest refutation, however, can be made on the basis of the assessment of the effectiveness of the experimental manipulations. Other aspects of institutionalization—unrelated to organizational context—were found to covary with degree of institutionalization: certainty of accuracy, reports of difficulty in judging light movement, and expectations that answers should be the same as the "experienced" subject.

Status value theories (Berger et al., 1966; 1972) would predict the results obtained for the office condition alone, though not fully since the naive subjects know they will occupy the office after one set of trials. However, since positions are differentiated, it could be argued that the occupant of the low position is more likely to be influenced by the occupant of the high position. However, the scope of the theoretical approach presented here is quite different, predicting not only the direction of influence in the office condition, but also the relative magnitude of influence which depends not on status value but on institutionalization.

Maintenance of Cultural Understandings

Maintenance frequently has been described as occurring only when direct social control is present. Direct sanctions produce compliance; as long as the expected behavior is in the actor's self-

Table 8. Analysis of Variance Test on the Difference in Response Level of the Same Subject in the Maintenance and Resistance to Change Experiments

Source of Variance	Sum of Squares	df	Mean Square	F	Significance Level
Between Groups	18.23	2	9.11	16.27	p < .001
Within Groups	23.53	42	.56		

interest, it will be maintained. Even the internalization and self-reward conceptions depend on direct sanctions to establish the behavior initially and/or to maintain the behavior in those actors not fully "socialized."

In the theoretical approach presented here, it is asserted that the more institutionalized, the greater the maintenance without direct social control. The effects of institutionalization can be seen most clearly when no sanctioning process is present. In the experiments reported here, social influence was present, but should operate uniformly in all conditions. The differences found, then, can be attributed to the relatively high dependence of acts low on institutionalization on social control mechanisms compared to the strikingly low dependence of acts high on institutionalization. The greater the degree of institutionalization, the less likely sanctions will exist. For example, laws regulating black-white interaction in the South were enacted only after the institution of slavery was challenged (Woodward, 1957).

Resistance to Change

Resistance to change is fundamentally affected by institutionalization, regardless of sanctions. The confederate's below-the-baseline responses serve to positively sanction lower responses by the subjects, yet it was found that only when the degree of institutionalization was low (the personal influence condition) did this sanctioning cause the subjects to reduce their response to below the baseline.

These results are, on one level, nonintuitive, since the subjects closer in response level to the confederate change the most. Subjects in the personal influence condition essentially adopted the new judgment standard: the situation was redefined. However, those subjects farther from the confederate's response level changed much less. As predicted, they resisted the confederate's attempt to redefine the situation.

The results of this experiment contradict other approaches most directly. In other approaches, resistance to change, regardless of source or content, comes di-

rectly or indirectly from the strength of the previous sanction. The subsystem approach assumes that resistance to change is a function of the distribution of rewards; if more rewards are associated with one action than with another, the more highly rewarded action will be exhibited. Therefore, those actions that are more highly rewarded will be more resistant to change. The normative framework approach argues that resistance to change is a function of internally generated motivation, either internalization or self-reward. Generally, this internal motivation is seen as deriving from previous sanctions applied to some actions and not to others. Neither of these traditional approaches to institutionalization could predict or explain the results obtained in the Resistance to Change Experiment.

General Implications

The findings reported in this paper are, thus, both consistent and inconsistent with previous arguments, serving to modify parts of the traditional approaches to institutionalization. However, the findings reported here do not suggest rejection of the traditional approaches but, rather, serve to conditionalize them by restricting the set of situations to which they apply. That is, it is not that these other approaches should be rejected but, rather, that the class of situations to which they apply should be more precisely specified. These other approaches do not deal adequately with highly institutionalized action: the mechanisms they use are more important when the degree of institutionalization is low.

The theoretical approach developed in this paper, based on the ethnomethodological approach, provides a more complete explanation of highly institutionalized action. In three experiments, persistence of cultural understandings has been shown to vary directly with the degree of institutionalization. The degree of institutionalization, depending on personal influence, organizational context or office directly affected three major aspects of persistence: generational uniformity, maintenance and resistance to change. Thus, a theory which explains highly in-

stitutionalized action also permits more accurate and complete predictions of cultural persistence.

In conclusion, the findings reported in three experiments provide strong and consistent support for the predicted relationship between degree of institutionalization and cultural persistence. As predicted, it was found that the greater the degree of institutionalization, the greater the generational uniformity of cultural understandings, the greater the maintenance without direct social control, and the greater the resistance to change through personal influence.

SOCIETAL REACTION TO DEVIANTS: THE CASE OF CRIMINAL DEFENDANTS *

ILENE NAGEL BERNSTEIN
WILLIAM R. KELLY
PATRICIA A. DOYLE
Indiana University

American Sociological Review 1977, Vol. 42 (October):743-755

Recent reformulations of the societal reaction theory argue that the thesis is a perspective rather than a theory, and that the perspective is meant to provide a set of sensitizing concepts to those researching deviance. This research examines the degree of congruence between hypotheses deduced from those assertions and a set of real world occurrences. Data for a sample of male defendants charged with felony offenses are examined to estimate the effects of (1) deviants' social attributes, (2) the specific societal reactors, (3) the values placed on certain offenses and (4) the organizational imperatives of the deviance-controlling organization, controlling for the alleged offense, on the probability of being labeled and sanctioned for deviant behavior. Our analyses indicate that characteristics associated with the alleged offense account for more of the explained variance in the labeling decision examined here (full prosecution) than in the sanctioning (sentence severity) decision. Moreover, while we find the deviants' social attributes do have some significant effects, relative to the effects of other variables, these effects are small and not always in the predicted direction. We suggest the interactionist perspective shift its focus toward greater attention to organizational imperatives and the values and expectations of those meting out the societal reaction as key variables explaining the imperfect correlation between deviant acts and the reaction to same.

Beginning with the work of Tannenbaum (1938) and Lemert (1951), a central concern for the study of deviance has been the delimitation of factors that affect the decisions and actions of deviance-controlling organizations and the conse-

quences of these decisions and actions for persons labeled as deviants. This concern is motivated by a theoretical interest in the way in which discretion is manifested in the societal reaction to deviants (Pound and Frankfurter, 1922; Becker, 1963; Turk, 1969) and by a methodological interest in the role of discretion in the production of deviance statistics and deviance categories used in sociological research (Garfinkel, 1956; Kitsuse and Cicourel, 1963).

While interest in the manifestation of discretion continues, it is now generally agreed that the core writings articulating the societal reaction thesis should not be

* Partial support for this research was provided by a Daniel and Florence Guggenheim Fellowship to the senior author during her year of residence at Yale Law School. Special thanks are extended to the Vera Institute of Justice for collecting these data, and to Martin Barr, Lucy Friedman, Arlene Gens and Charles Kuhlman of the Vera staff for their valuable comments. Thanks too to Peter Burke, John Cardascia, Jan Leung, Barbara Schulz, Jackson Toby, Austin Turk and Stanton Wheeler for comments on earlier drafts of this manuscript.

treated as a formal theory. Rather, it is argued that these writings provide a set of "sensitizing concepts" relevant to the study of deviance (Schur, 1971; Becker, 1973). However, acceptance of the idea that what was formally termed "labeling or societal reaction theory" is not a *theory*, does not preclude the still unmet need for empirical examinations of the congruence between hypotheses deduced from these "sensitizing conceptions" (or, as Becker, 1973, terms it, interactionist perspective) and real world occurrences. It is to this task that this research is addressed.

A review of the works generally construed as representative of the societal reaction thesis (e.g., Lemert, 1951; Becker, 1963; Erikson, 1964) as well as the recent modifications and reformulations of same (e.g., Lofland, 1969; Schur, 1971; Becker, 1973; Goode, 1975) reveals consensus in emphasis, and relative agreement on a core set of assertions. The emphasis mandates that the study of deviance include attention to the process by which purported rule violators come to have deviant status conferred upon them. The core assertions include: (1) the definition of persons as deviant is a constructed definition resulting from a set of interactive processes (Lofland, 1969; Becker, 1973; Goode, 1975); (2) the societal reaction to deviants is not a direct result of the alleged deviant act (Erikson, 1964; Becker, 1963; 1973; Kitsuse and Cicourel, 1963; Schur, 1971); (3) the societal reaction to deviants varies with the social attributes of the alleged deviant (Becker, 1964; Quinney, 1970); (4) the societal reaction to deviants varies with the organizational imperatives of the deviance-controlling organization (Schur, 1971; Becker, 1973), with the persons doing the reacting (Becker, 1973), with the expectations and values of the reactors (Turk, 1969; Schur, 1971), with the deviants' ability to avoid the imposition of the deviant label (Schur, 1971) and with a variety of other ancillary factors (Goode, 1975).¹

¹ In addition to the above, there are a set of core assertions that relate to the effect the deviant label has upon subsequent deviant behavior. Our analyses do not address these issues. For a review of research that does, see Gove (1975).

Despite the relative agreement as to the emphasis and core concepts, there is little agreement between proponents and critics as to what are the empirically testable hypotheses logically deduced from these concepts. For example, Tittle (1975) argues that one of two theoretically provocative hypotheses is that social attributes of the alleged deviant explain *more variance* in the societal reaction than does the alleged rule-violating behavior. Schur (1975), however, contends that the very hypothesis that Tittle rejects as uninteresting is the one in which interactionists are interested, i.e., social attributes of the alleged deviant affect the societal reaction to deviants (regardless of the size of their effect relative to other variables). Schur concurs with Becker (1973) in arguing that the intent of interactionists is to expand the amount of explained variance in the societal reaction, not to restrict it to a thesis that makes the social attributes of the alleged deviant the major determinative factor. This disagreement spills over to the evaluation of the extant research. For example, in Tittle's (1975) review of research on the reaction to alleged law violators, he concludes there is little support for the hypothesis that social attributes of the deviant explain more variance than the alleged criminal act. Furthermore, he cites Hagan's (1974) review of extra-legal attributes and sentencing to buttress his inclination to conclude that the data don't support his version of the interactionist thesis. However, Tittle's acknowledgement of the methodological limitations of the extant research, coupled with the disparity between his and Schur's definition of the critical hypothesis, precludes him from reaching definitive conclusions about the explanatory power of the interactionist perspective.

Insofar as the interactionist perspective (whether a theory, a set of sensitizing concepts, or a perspective) continues to dominate deviance research, we think it would be most fruitful to examine the degree to which empirical data are consistent with the hypotheses that most closely conform to the assertions of those proposing them. By so doing, we hope to broaden the knowledge base and reduce

the likelihood that empirical findings will be disregarded on the basis of their addressing the wrong questions.

In accordance with our review of interactionist writings, we take a central question to be, controlling for the alleged deviant act, what other factors account for explained variance in societal reactions? Specifically, we deduce the following hypotheses to explore the degree to which interactionists' assertions properly specify and emphasize the relevant determinative factors: (1) indicators of the alleged deviant act don't account for all of the explained variance in societal reactions; (2) social attributes of the alleged deviant account for some of the explained variance (the expectation being that the socially disadvantaged will be responded to more negatively); (3) organizational imperatives account for some of the explained variance, as do the individual persons doing the reacting, the values of the reactors and other ancillary factors.

Before proceeding, we need to acknowledge an obvious leap we make here from the interactionists' assertions to our own specification of research questions. Recall that the emphasis mandated was that the study of deviance attend to the process. Accordingly, a methodological preference for field observations and qualitative analyses is often expressed. While we grant the value of these methods, we contend that quantitative analyses of the same or related questions are not precluded. Gibbs (1972:47), for example, argues that if the ratio of persons formally identified as deviants to those labeled as deviants (e.g., arrested/convicted) is not 1:1, the basis for that disparity needs to be empirically explored. Becker (1973:16-7), Kitsuse (1975) and Schur (1975) articulate a commitment to the value of quantitative analyses that address interactionist questions. The most compelling justification, however, comes from Goode (1975:579) in his call for probability estimates of varying societal reactions, given various conditions: "A completely situational view of deviance can be intellectually paralyzing. The probabilistic view rescues us from the solipsistic logical extreme of absolute situational relativity. . . ." Thus, while we have leaped from the interactionist's as-

sertions to a set of questions couched in terms most congruent with multivariate analyses, the justification for so doing can be well documented.

Research Setting

The criminal justice system is a strategic arena in which to research interactionist questions because there is general consensus that criminal justice decisions, e.g., arrest, severity of sentence, are labeling decisions, i.e., decisions that can be taken as valid indicators of formal societal reactions. Moreover, criminal justice decisions occur in sequence. As such, in examining the bases for one decision, one also can examine the effect of a prior decision. To illustrate: in examining the bases for sentence severity, one can consider a defendant's release status prior to trial, a status that itself represents the culmination of a prior deviance processing decision. Finally, the fact that the criminal justice system operates like a sieve, filtering out defendants at each stage of the process (Blumberg, 1967; Rosett and Cressey, 1976) makes it amenable to analyses organized more like a tree than a table. Schur (1971) and Hagan (1974) underscore this point, noting that the processing of deviants involves a series of decision-making stages, and not all deviants continue through all of the stages. As such, processual analyses that begin with a sample of deviants, and examine sequential decisions where the sample for whom the decision is relevant decreases with each new decision, can bring to light the manifestation of discretion at different stages in deviance processing.

Sample

Our sample consists of all males arraigned in a city in New York State, from December, 1974 to March, 1975, whose most severe arrest charge was a *felony charge*, whose cases were not disposed of at first court presentation² and whose

² Seventeen percent of persons arrested for felonies are finally disposed of at their first court presentation, i.e., within 24 hours after the arrest.

cases were finally disposed of in criminal court within the four-month period of observation, by a judgment other than an acquittal, by judges who disposed of more than one percent of the cases ($N = 1,213$).³ For each of these 1,213 defendants, court record data were recorded daily for the judicial disposition of every court appearance. Data on the defendant's criminal history were recorded from state criminal records and data on defendant's demographic characteristics from personal interviews conducted during the 6–24-hour period immediately following the defendant's arrest (while he was in custody) and preceding his first arraignment hearing. Data on the characteristics of the criminal offense were obtained from court records.

In addition to the above, complementary qualitative data were collected by the senior author through court observations and interviews with judges, prosecutors, defense attorneys and auxiliary court personnel. The qualitative observations were used to determine (1) which exogenous variables to include, (2) the appropriate way to code these variables and (3) major interpretations of results.

Since the disposition process is so truncated, we analyzed data for this group separately. Our findings indicate that the factors that affect the three disposition decisions for these defendants are quite different from those affecting the same decisions for those not so rapidly disposed. These additional data may be obtained from the senior author.

³ The criminal court in the city from which these data come is a misdemeanor court. As such, only cases where the conviction charge is less than a felony as included here, despite the fact that the arrests were all for felonies. However, we can estimate that our sample of felony cases represents about 92% of total felony arrests, since we know that in the observation period, only 8% of the cases were waived to the grand jury for indictment and supreme court processing. Female defendants are excluded because of the developing literature on women in crime (e.g., Brodsky, 1975; Simon, 1975). Since we could not attend to the theoretical propositions of that literature, we exclude them here. Similarly, persons arrested for misdemeanors are excluded here and analyzed in another paper. Acquittals were excluded because there were too few cases acquitted. Finally, we only include cases disposed of by judges who disposed of more than 1% of the cases such that we could reduce the number of relevant judges from 52 to 17, clearly a more manageable number.

Endogenous Variables

Three endogenous variables are examined. While these three variables don't represent all of the decision stages, they do represent the critical formal reactions of the collective audience once the deviants have been brought before the deviance-controlling organization.

For all defendants in our sample ($N = 1,213$), we examine the decision to fully prosecute a case or to terminate the case by dismissal (Y_1). Since nearly forty percent of our defendants (and comparable proportions of other samples of defendants, e.g., Hagan, 1975; Zeisel et al., 1975) are dismissed, research examining the bases for sentencing decisions must examine the bases for the prior decision that determines whether a defendant will be eligible for sentencing. With the exception of Burke and Turk (1975) Hagan (1975) and Zeisel et al. (1975), most prior research on sentencing (e.g., Chiricos and Waldo, 1975; Swigert and Farrell, 1977) ignores this important prior selection process.

For those defendants whose cases are not terminated by a dismissal ($N = 733$), we examine whether the defendant was adjudicated guilty and sentenced, or whether the defendant was adjudicated guilty but not formally convicted and thus not subjected to a sentencing decision (Y_2). Our data come from a criminal justice system that has formalized this second decision in its ACD statute (adjournment in contemplation of dismissal). Defendants whose final disposition is an ACD are adjudicated guilty but not formally convicted unless they are rearrested and charged with a new offense in the six-month period following the original ACD disposition. Since their record carries no conviction, they receive no sentence. This is a particularly interesting labeling decision since *both* those given ACDs and those moved on for sentencing are presumed guilty as charged.

Finally, for those defendants whose cases were not terminated by a dismissal or an ACD ($N = 510$), we examine the severity of the sentence meted out as a measure of the severity of the formal societal reaction (Y_3). Sentence severity is

analyzed as an ordinal scale (see Y_3 , Table 1). The determination of the order is in accordance with that specified by the judges, prosecutors and defense attorneys whom we interviewed.

Exogenous Variables

Since we define our research as exploratory, a large number of exogenous variables are examined in the preliminary stage of our analyses. We included variables related to the defendant's social attributes, e.g., race, age, education, marital status; variables that might determine the reactor's expectations for and perceptions of certain deviants, e.g., the defendant's prior criminal record; variables related to the organizational imperatives of the deviance-controlling organization, e.g., the defendant's cooperation during the arrest, the defendant's acceptance of guilty plea offers; variables related to the individual's doing the reacting, e.g., judges; and variables summarizing the results of prior processes, e.g., the defendant's release status pending his final disposition. In addition, variables related to the alleged offense, e.g., the type of crime, number of charges, and severity of the charges are included. A list of exogenous variables and the way in which each is coded is presented in Table 1.

Analyses

The data are analyzed using dummy variable regression procedures. The general appropriateness of these techniques is reviewed in Cohen (1968) and Kerlinger and Pedhazur (1973). Since we define our research as exploratory, nominal variables are effect-coded (Kerlinger and Pedhazur, 1973:172-85). That is, comparisons are made between each category and the mean of the other categories, rather than between one category and some arbitrarily selected left-out category.

Since there are no published data on a number of variables here considered, we examined first the zero-order correlations between all of the exogenous variables and the three endogenous variables. No problems of multicollinearity were appar-

ent. In the regression equations on which Table 2 is based, only variables whose net effects were statistically significant at .10 were included.⁴ An exception to this is that certain variables were deemed control variables, e.g., the severity of the most severe arrest charge and the type of crime; as such, they were entered into every equation. Finally, the regression coefficients presented represent the coefficients from the equations where the appropriate judges have been stepped in. A comparison of the coefficients before and after controlling for judges revealed little changes in the coefficients. However, the procedure was kept to provide a measure of control for variation by judge and an estimate of the increased variance explained by judges.

Results

Table 2 presents the regression coefficients for those exogenous variables that had net effects on the first endogenous variable (Y_1). If a variable appears in Table 1 and not in Table 2, that variable did not have a statistically significant effect.

According to Table 2, the likelihood of being dismissed is increased if: (1) the defendant's most serious arrest charge was a burglary or assault charge; (2) the defendant's total number of arrest charges was lesser rather than greater; (3) the defendant was detained in jail while awaiting his final disposition; (4) the defendant's felony charge was reduced to a misdemeanor at the latest possible opportunity, i.e., at or after his preliminary hearing.

Since dismissal is purportedly a function of the strength of the evidence (Miller, 1970), we discuss first those findings interpretable as reflective of evidentiary concerns. The fact that we find defendants charged with burglary more likely to have their cases dismissed may be a function of burglary cases being difficult to prosecute

⁴ Our selection of .10 reflects our concern for using too stringent criteria in exploratory work, the possibility of a type II error, and a concern for the continuing debate about the use of significant tests (Morrison and Henkel, 1970) as the determinant of which variables to include in a model.

Table 1. Variables, Notation, and Frequencies

Notation	Variable	Scale	Frequencies (1,213)
Y ₁	Disposition— Dismissal	Not dismissed (0) Dismissed (1)	60.5% 39.5%

		6+ months (1)	29%
		Unempl. less than 6 mos. (2)	29%
		Empl. less than 6 mos. (3)	13%
		Employed 6+ mos. (4)	29%
X ₁₅	Weighted Index of Prior Convictions ^e	Interval Scale 1-36	$\bar{x}=2.37$
X ₁₆	Elapsed Time since Most Recent Arrest ^f	0-3 days (1)	0.5%
		4-180 days (2)	15.5%
		181-365 days (3)	6.0%
		366-729 days (4)	7.0%
		2-5 years (5)	9.0%
		5+ years (6)	26.0%
X ₁₇	Pretrial Release Status ^g	Detained more than or equal to 30 days (1)	16.5%
		Detained less than 30 days (2)	25.0%
		Released on bail (3)	2.0%
		Released on personal recog. (4)	53.5%
X ₁₈	Felony Charge Reduced to Misdemeanor at First Presentation ^h	Reduced at adj. after arraignment (-1)	59.0%
		Reduced at prel. hearing (0)	34.0%
		Yes (1)	7.0%
X ₁₉	Felony Charge Reduced to Misdemeanor at Preliminary Hearing ⁱ	Reduced at adjournment after arraignment (-1)	59%
		Reduced at 1st pres. (0)	7%
		Yes (1)	34%
X ₂₀	First Arrest	No (-1)	64%
		Yes (1)	36%

^a Severity of the arraignment charge was examined separately from the arrest charge because the arraignment charge is the charge for which the defendant was prosecuted, and it may differ from the arrest charge. Severity is coded here and in X₁ from least to most severe, and the severity code corresponds to the most severe charge if there was more than one charge.

^b The type charge for X₅-X₇ was coded in accordance with the most severe arrest charge.

^c Race/ethnicity was also examined as Black/White/Spanish. Since the difference in effects was White/Black or Spanish, the white-nonwhite code is presented.

^d Time employed is used instead of income because there is very little variation on income in this sample and because employment stability rather than income was observed to be a question often raised in court.

^e Prior felony convictions were given 3 points, prior misdemeanor convictions 2 points and prior violations 1 point. The index is the sum of these scores. The data were analysed with prior convictions differentiated as well.

^f The arbitrary coding here was exactly as the data were collected by the pre-trial services agency.

^g The defendants' status while awaiting final disposition was broken into these four categories because prior research has been criticized for failing to differentiate between those detained for longer versus shorter periods of time.

^h The first presentation is the first arraignment hearing.

ⁱ The preliminary hearing is the last point at which felony charges can be reduced in criminal court. If the felony charge remains, the case is waived to Supreme Court.

successfully. Many burglaries are committed at times and in places where eyewitnesses are not present. The absence of witnesses naturally reduces the strength of the evidence. Our finding that defendants who have less rather than more arrest charges are more likely to be dismissed also may be related to evidence, since those with more charges are often those against whom a stronger case can be made. Finally, our most important finding, i.e., that defendants whose felony charges are not reduced until the final opportunity are more likely to be dismissed, also may be construed as reflective of evidentiary problems. These defendants have continued in the court process longer than their counterparts; as such, the standard for continuance of the case has increased. Specifically, Zeisel et al. (1975:134) note: "The standard for sufficient evidence to continue a case becomes more stringent as the criminal process proceeds. To sustain initial prosecution, 'probable cause' is sufficient evidence; eventually [however] proof of guilt 'beyond a reasonable doubt' is needed."

While the findings discussed above are interpreted as reflecting problems of evidence, for sociology the interesting findings are those that don't fit neatly into that interpretation. The question is, to what degree do they fit the interactionist perspective?

Starting with the easiest variable, our finding that individual judges do significantly affect the dismissal decision (see note, Table 2) is consistent with prior research (Hogarth, 1971) and with the interactionist thesis (Becker, 1973) that those playing the role of societal reactor significantly affect the nature of the reaction. In the absence of additional data beyond the judges' identification, we can't explain what it is about individual judges that correlates with the dismissal decision. Future research should make this a priority concern.

Our finding that defendants charged with assault are more likely to be dismissed may reflect the lesser value placed on interpersonal violence when it occurs among minority groups. While we lack individual data on victims, our court observations revealed that almost all of the

assault cases prosecuted were assaults between persons of the lower classes who predominate in the catchment area served by this court. Like Garfinkel (1949) and Bensing and Schroeder (1962), we suggest that interpersonal violence evokes a lesser response when both the defendant and the victim are socially disadvantaged because there is less concern for disadvantaged victims. This finding is consistent with the interactionist thesis that the "value" of the offense, as perceived by the reactors, affects the determination of the societal response (Schur, 1971).

Finally, our finding that the defendant's release status prior to disposition affects the likelihood of dismissal is of interest, since we find being *pre-trial detained increases the likelihood of being dismissed*. Thirty-nine percent of those detained in jail while awaiting their final disposition are ultimately dismissed. Admittedly, this seeming inconsistency is possible while still operating within legal statutes. However, it is ideologically problematic to note that so many persons are detained while awaiting dispositions for charges for which they will ultimately not be convicted. Our observations suggest that some court agents are using court processes as sanctions. That is, they assume that defendants who have been detained already have been sanctioned. To save the court further expenditures of time and money, the detention experience is treated as having provided the necessary "taste of jail" to deter future crime. While our observations of the treatment of the detained affirm the appropriateness of the assumption that they have been sanctioned, the question is whether some of these dismissals are obscuring a kind of discrimination against the economically disadvantaged. To elaborate: if the defendant was detained because he couldn't post bail and his subsequent dismissal reflected a presumption of his innocence, his inability to post bail would have caused him to be severely sanctioned. The subsequent dismissal of his case obscures the fact that he has been punished unnecessarily. Ultimately, to determine whether this kind of discrimination is widespread, one needs to know the basis upon which the pre-trial release decision

was made. Again, future research should probe this question in greater depth.

To summarize for this first dependent variable, i.e., the dismissal decision, we find the assertions of the interactionist perspective to be modestly supported. While we do find factors associated with the alleged offense don't account for all of the explained variance, almost all of the explained variance can be interpreted to be a function of the strength of the evidence. Unless the strength of the evidence can be shown to be related systematically to extra-legal considerations, the argument that dismissal decisions are based on misappropriated discretion has to be seriously questioned. Furthermore, the variables examined here to indicate the defendant's social attributes (e.g., race, education) are found to have no significant effects. The above notwithstanding, we do find that the persons doing the reacting (e.g., judges), the values attached to specific types of crimes (e.g., assaults), the organizational imperatives of the court (e.g., dismissal of persons detained before trial) and statuses resulting from prior decision processes do significantly affect the societal reaction, controlling for the alleged deviant act. These effects, however, are all relatively small.

Table 2 also presents the regression coefficients for those exogenous variables that had net effects on the second endogenous variable (Y_2). The decision to adjourn a defendant in contemplation of a dismissal is increased if: (1) the defendant's most serious arrest charge is a drug charge; (2) the defendant's total number of arrest charges was lesser rather than greater; (3) the defendant was *not* charged with "resisting arrest"; (4) the defendant has less rather than more prior convictions; (5) the defendant had never been arrested prior to this arrest; (6) the defendant was released from custody pending his final disposition.

Our finding that defendants who have "cleaner" prior criminal records are more likely to be favored with this ACD disposition suggests differentiation on the basis of accumulated disadvantaged status. That is, those with heavy prior records, having previously been adjudicated guilty, have already accrued a disadvantaged

label. Whether differentiation on the basis of this prior disadvantaged status is discriminatory depends on whether the status of "prior convicted offender" was ascribed or achieved. To the extent that one's conviction for a prior crime was not entirely a function of the alleged offense, the negative effect of a prior record can be interpreted as partly discriminatory. Until such time as we can partial out achieved disadvantaged status from ascribed, the issue of infinite regress remains problematic.⁵

Our finding that defendants charged with resisting arrest are less likely to be favored with this disposition is consonant with the interactionist thesis that the organizational imperative to maintain good relationships among criminal justice personnel affects societal reactions. Blumberg (1967), Chambliss and Seidman (1971) and Rosett and Cressey (1976) underscore the importance of the police to the criminal justice system and the need to sanction those who counter police authority.

Our finding that defendants who are released while awaiting their final disposition are more likely to be given ACD dispositions is consistent with the Wald and Freed (1966) and Roballo (1974) thesis that defendants carrying the label of "pre-trial detainee" are processed with an additional negative status. The fact that a defendant was not released pending disposition signifies that the defendant was deemed a poor flight risk, a danger to society and/or economically disadvantaged. If a prior set of societal reactors responded negatively to the defendant, it might be organizationally functional to maintain consistency in decision making,

⁵ The problem of infinite regress is important because the law provides for consideration of decisions resulting from prior processing, e.g., ex-convict status. However, since we know that whether someone carries forward "ex-convict" status is not entirely a function of prior deviant behavior (Bernstein et al., 1977), there begins to be a meshing of legal and extra-legal considerations. Moreover, since discretion operates at every stage of the process, one can always argue that some prior process problem of infinite regress should be kept in mind to stimulate new lines of inquiry. It should not, however, be used to discount findings that fail to account for the entirety of processing.

thus the denial of the favorable ACD disposition. Alternatively, social typing (Schur, 1971) might be occurring wherein the defendant's release status prior to disposition is treated as a category defining a set of appropriate responses. Since being detained prior to disposition is the least favorable category, a negative response to those so categorized becomes understandable.

Finally, as before, we find those acting out the part of the societal reactors, i.e., the judges, have a significant net effect on the ACD decision.

To summarize, whereas the dismissal decision was largely determined by consideration of factors related to evidence, our analysis of the decision to favor a defendant with a "second chance" finds somewhat stronger evidence in support of interactionist assertions. Variables associated with the alleged offense neither account for all of the explained variance nor have the largest effects. Rather, it seems that organizational imperatives (e.g., deference to the police), the individuals who are reacting, and negative status labels carried forth from prior decision processes (e.g., prior criminal record) play the major role in determining whether a defendant will be adjourned in contemplation of dismissal. As before, we must reiterate the very notable lack of significant effects for the social attributes of the defendant here examined.

Finally, we present the regression coefficients for those exogenous variables that had net effects on the third endogenous variable (Y_3). According to Table 2, the likelihood that a convicted defendant will receive a *more severe sentence* is increased if: (1) the defendant is charged with robbery; (2) the defendant has a heavier record of prior convictions; (3) the defendant has been employed for a *longer* rather than shorter period of time and (4) the defendant is *white*. The likelihood of receiving a *less severe sentence* is increased if: (1) the defendant is charged with assault; (2) the defendant has no prior arrest record; (3) the defendant has maintained a "clean record" for a longer period of time and (4) the defendant was released from custody pending his final disposition.

Since the direction of these findings is

identical to those earlier noted and we have already provided interpretative comments, we limit our discussion to those findings upon which we have not previously commented. We interpret the finding that defendants whose most serious arrest charge is robbery are more severely sentenced to be a function of the high value placed on robbery offenses in this geographic area, at this point in time. Public concern for increasing robberies, especially violent robberies against the elderly and the handicapped, was extremely high when these data were collected. Thus, the value attached to the crime may explain the severe response to those so accused (Turk, 1969; Schur, 1971).

The finding that white defendants, as well as defendants who have been employed for longer periods of time, are more severely sentenced is unexpected. While these effects are smaller than those of other exogenous variables, they are statistically significant. Clearly, they may be due to chance, given the large number of variables considered. However, on the assumption that the findings are reliable, we advance the following as a possible explanation. According to some of our interviewees, some judges and prosecutors assume that nonwhites commit crimes because the nonwhite subculture accepts such behavior. These subcultural differences are considered by the judges and prosecutors, thereby making the offenses of nonwhites seem less pernicious. However, no comparable "account" is available for white defendants. Expectations for them are higher and, as such, their failure to meet such expectations may appear more noxious—thus, the more severe sanction. The same explanation was put forth for defendants holding steady jobs. While this line of interpretation is speculative, future researchers should make a priority of the collection of data that would allow us to estimate the degree to which the expectations and tolerances held for certain groups of deviants and deviance affect societal reactions.

To summarize, the severity of the sanction meted out to convicted defendants is not a direct result of the alleged offense. While none of the effects are large, the determination of the harshness of the re-

sponse is affected by consideration of the public concern for particular offenses, the expectations held for various groups of deviants, and the status labels that defendants carry forth from prior stages of deviance processing.

Conclusion

We began with the presumption of an imperfect correlation between deviant acts and the societal reaction to those acts. Taking the broad view that there are a variety of factors that account for that independence, we analyzed three sequential societal reaction decisions. Our data indicate, first, that the variety of contingency factors emphasized by interactionists as explaining the independence between deviant acts and the reaction to same explain more variance in later rather than earlier deviance-processing decisions. That is, extra-legal factors explain more variance in sentence severity decisions than in prosecution and adjudication decisions. However, since we have not here analyzed the entirety of decisions, i.e., decisions that precede the dismissal decision (e.g., arrest) nor those following the determination of sentence decision (e.g., parole), we limit our conclusion to an assertion that the amount of variance explained by characteristics of the deviant act varies with the decision being made and the point in time at which the decision occurs. This suggests that comparable data sets need to be analyzed for all the deviance-processing decisions in sequence. When this task is accomplished, we should be able to determine whether the independence between deviant acts and societal reactions increases or decreases as one moves through deviance-processing stages.

Second, the emphasis that interactionists place on the role of the deviants' social attributes in explaining variation in societal reactions seems very much overstated. Our finding that age, education, employment stability, marital status, and race have no effects on the first two societal reactions decisions, and only small effects on the third societal reaction decision, suggests that the theoretical focus requires considerable shifting. Spe-

cifically, we interpret our findings to suggest that greater attention to be paid to (1) organizational imperatives of the deviance-controlling agency, (2) the expectations and values of those participating in the decisions and (3) the role of accumulated disadvantaged statuses acquired in prior deviance-processing stages. While our results affirm the assertion that these factors significantly affect societal reactions, they do not provide the depth needed to construct a theory explicating the conditions under which these factors are more or less salient and when salience represents systemic discrimination. Future research should make this a priority.

Finally, in terms of sociological theory, while we find the thrust of the interactionist perspective and its core assertions are consonant with real world occurrences, the perspective is so broadly stated that it precludes the refinement necessary for the assertions to be linked into some useful theory. Accordingly, we suggest more empirical exploration be undertaken, with an eye toward the emergence of a grounded theory of deviance. To the extent that the results of empirical research can delimit the various stages of deviance processing, and the precise degree of, and bases for discretion at each stage, we can begin to articulate an empirically based theory.

PATTERNS OF URBAN DOMINANCE: THE U.S. IN 1890

MARK ABRAHAMSON

University of Connecticut, Storrs

MICHAEL A. DUBICK

University of Minnesota

American Sociological Review 1977, Vol. 42 (October):756-768

The major thesis of this paper is that macroanalyses of urban social organization have unduly exaggerated the importance of trade and commerce as the foundations of a division of labor among cities. This division of labor and the capacity of cities to influence each other differentially are examined as resting upon a convergence among fiscal-commercial activities, plus intellectual, cultural and organizational activities, and transportation and communication. This multifaceted conception of urban dominance stresses how different kinds of activities are associated with different geographical spheres of influence, resulting in three distinct types or dimensions of dominance: national-international, regional and local. Examination of U.S. cities in 1890 indicates two different functional and geographical distributions of regional and national dominance. They are associated with different patterns of regional integration and with variations in the economic development of regions. The types of dominance are also seen to exhibit substantial historical continuity between 1890 and 1970, with the multifaceted measure providing much better predictions than the financial measure.

An intimate historical association among the development of technology, the increased complexity of social institutions, and the growth of cities—in both size and functions—has been described repeatedly (Mumford, 1938; Meadows, 1958:141-7; Weber, 1958). Thus, terms like “urban society” and “urban systems” provide shorthand ways of referring not only to the major changes that have occurred in cities, but in technology and in institutions as well. One result of these converging forces is an urban social organization that has been the object of a half century of continuing study, though from markedly different perspectives. At a microsocial level, following Wirth (1938:1-23), Thomas (1923) and others, the focus has been upon interpersonal relationships and situational meanings, with the urban society viewed as a generator of distinctive cultural values and social norms. At a macrosocial level, the pervasive perspective has been ecological and structural, stressing the interdependence, specialization and division of labor within an urban system (cf. Duncan et al., 1960; Gibbs and Martin, 1962: 667-77; Duncan and Lieberman, 1970).

While it has been claimed that distinctions between the two perspectives have been exaggerated (cf. Schnore, 1961:128-49), it is nevertheless true that

very few studies have attempted to view the interactional and cultural aspects of urban societies in structural terms or, conversely, to relate the structural features of urban systems to values and norms. (Some exceptions to these trends include Pred, 1966; Abrahamson, 1974:376-383; Fischer, 1975:520-32.) The most ambitious objective of this paper is to suggest the fruitfulness of integrating aspects of the two historically separated perspectives.

At a macrosocial level, efforts to analyze the distinctive features of urban social organization frequently have focused upon the concept of urban, or metropolitan, dominance. As utilized, dominance has had two interrelated referents: (1) a view of cities as the loci of major activities and (2) a view of large-scale urbanism as involving a division of labor among cities, with a city's location in the division of labor implying differential capacities to influence activities or set the conditions of operation in other cities (Hawley, 1971). Since Plato and Aristotle, theorists have speculated about such patterns of dominance (Wirth, 1937:493-509); but, with respect to contemporary urban systems, there are several pioneering studies that have come to be regarded as landmarks.

The first of these was probably Gras'

(1922) early study. He maintained that technology, economic systems and social organization tended to converge historically into five major constellations, or phases, and that these phases described the history of Western civilization. The final phase, termed the "metropolitan economy," involved large cities which were the loci of extensive trade and commerce. In comparing cities, Gras emphasized the dominance dimension which he viewed as primarily fiscal and economic in nature. "What counts most," he concluded, "is commercial dominance over a wide area" (Gras, 1922:184). The boundaries of this subordinated "hinterland" were not well delineated, though he did distinguish between types of trade according to whether they tied a city into a local (metropolitan) or an extended (national) economy.

McKenzie's important contribution placed dominance into an explicit ecological framework then being developed at the University of Chicago (cf. Faris, 1967). Based upon transportation developments, notably the automobile, McKenzie (1933:7) saw the contemporary city as "able to extend the radius of its influence . . . throughout surrounding territory." Like Gras, he stressed an economic interpretation of dominance, an emphasis which was highly compatible with the analogy drawn between plant and animal communities, on the one hand, and the metropolitan or human community, on the other. Thus, people striving to "maximize their livelihoods" in a metropolitan community became equivalent to a collective response or adjustment to habitat in a biotic community. Also, McKenzie saw the basic ecological features of the metropolitan community as the result of people trying to maximize their livelihoods while minimizing their efforts.

Bogue (1949) added clarity and precision to the study of urban dominance, while retaining an explicit ecological perspective. His detailed and extensive classification of American cities also emphasized the economic realm, utilizing wholesale and retail trade, services and manufacturing as the indicators of dominance. Aside from their ready availability,

he justified their use because they were indicators of human sustenance. In examining his detailed sectors and distance zones, Bogue also confronted the issue previously encountered by Gras and McKenzie, namely, the uncertain boundaries of a metropolitan area's dominance. He noted that some areas' influence transcended across adjacent metropolitan areas. Hence, some type of division of labor among cities in the national economy must occur, he concluded, and it must be analogous to the division of labor within metropolitan areas. Aside from offering this observation, however, Bogue did little to pursue its implications.

The ecological perspective on urban dominance, developed primarily during the second quarter of this century, continued to influence very strongly the direction of inquiry in the third quarter. In this later period, most of the research attempted either to document aspects of the Gras-McKenzie-Bogue paradigm (cf. Lieberman, 1961:491-6) or to clarify questions related to the measurement of dominance raised by their paradigm (cf. Carroll, 1963:166-73). The paradigm has been demonstrably fruitful, but it has remained conceptually narrow, with an overwhelming emphasis upon a commercial-economic conception of dominance, a conception which draws on a questionable "economic man" model (cf. Sjoberg, 1965:157-89). As a consequence of this emphasis, dominance theory has been viewed as applicable to an unduly limited range of problems. The strict commercial-economic interpretation of dominance also has helped to perpetuate the estrangement between ecological and other approaches to urbanism by implying that the ecologically salient concept of urban dominance was not relevant to analyses of cultural values, noneconomic institutions, or the like.

Multifaceted Dominance

We contend that financial, commercial or economic considerations have been overly emphasized. Their theoretical relevance is apparent and their utilization has been fruitful in clarifying a number of urban patterns. However, there are also

several decades of research and theory that suggest cities also to be important centers for intellectual and artistic creativity (Merton, 1964), the headquarters of nonfinancial as well as financial associations (Lieberson and Allen, 1963:319-25), centers for the innovation of new lifestyles (Becker and Horowitz, 1971:12-5), and so on.

The architects of the pervasive ecological model were themselves aware of noneconomic dimensions of urban dominance. Bogue (1949:23), for example, in the same paragraph that stressed sustenance indicators, explicitly noted the possible existence of dominance patterns that were less related to sustenance. Even more explicit was Burgess' (1925) view of the dominance of the central business district ("the nucleus") which he described as not only commercial, but intellectual, political and cultural. Over time, however, the commercial-financial emphasis of the ecologists led to the implication that the noneconomic aspects of dominance were little more than redundant by-products of the economic ordering of cities (cf. Duncan et al., 1960).

It is our hypothesis that while there is convergence among financial, intellectual, cultural and other aspects of dominance, their combination produces a ranking of cities that is different from that produced by one of them (such as the economic) alone. We further expect that this combined index of dominance will provide the best predictor of future city activities, even in a financial-commercial sphere. More fundamentally, we are beginning with the (traditional-ecological) assumption that there is a division of labor among cities and that a city's location in this division of labor determines its degree of dominance. However, we view this division of labor itself, and the consequent dominance of cities, as resting on a variety of activities rather than upon financial-commercial activities alone.

Types of Dominance

Related to the nature of dominance is the question of whether variations in the geographical scope of a city's sphere of influence should be considered a single

discrete variable. If so, then variations in geographical spheres can be viewed as the result of *quantitative* differences in the dominance-producing activities that are located in cities. If dominance over different sized geographical areas is associated with different kinds of activities, however, types of dominance should then be viewed as *qualitatively* different from each other. There are precedents for either view, though the quantitative assumption appears more congruent with a view of dominance as a limited, commercial-financial phenomenon.

Gras (1922), for example, saw local, as opposed to extended dominance as resting upon different types of trade (e.g., retail versus wholesale), and this distinction has resulted in two somewhat different rankings of American cities (Carroll, 1963:166-73). However, while McKenzie, Bogue, and later students of urban dominance sometimes made similar distinctions, the general tendency has been to view different geographical spheres as extensions along a unitary dimension. More of the same kinds of activities, it is therefore implied, would increase the geographical scope of a city's sphere of influence; and the kinds of activities singled out are commercial-financial. The compatibility of these two assumptions is illustrated by the Duncan et al. (1960:270) classification of San Francisco as a regional metropolis that is "nearly strong enough" in financial functions to qualify as a national metropolis.

Associated with the view of dominance as multifaceted, however, it is our hypothesis that different mixes of activities are associated with varying geographical spheres of influence. For example, the circulation of a city's daily newspaper in most instances, is, tied to a local metropolitan area. Differences in circulation, standardized for city size, might therefore reflect the local, but not extended dominance of most cities. On the other hand, scientific journals that are published in a city typically have a national and international audience. Variations among cities in this form of publication activity therefore might be indicative of extended dominance, but not local dominance.

It is our more specific contention that it

is fruitful to differentiate among three types of dominance: national-international, regional and local. The first type is named national-international in recognition of the fact that important relationships among nations tend to occur between their major national cities. Thus, major national cities are also simultaneously "world cities" (Hall, 1966). The second type of dominance, regional, involves influence over large geographical areas, but not entire nations. Historically, New England and the South are probably the most apparent examples of regions in the U.S. (cf. Vance and Sutker, 1954). While their boundaries may be fluid, the distinctiveness of regions is based upon specialized divisions of labor, common cultural orientations, and the regional or district organization of government and national organizations. We contend that while regional dominance might be viewed quantitatively as a lesser degree of national dominance, the different types of activities involved in each make them better viewed as two separate (qualitative) dimensions. For example, an increase in Atlanta's role as a Southern railroad center in 1900, or as a distribution center for the South in 1975, would not necessarily increase that city's national dominance. Finally, local dominance refers to the influence exerted over an immediately adjacent hinterland and corresponds roughly with SMSAs or urbanized areas. Conceptually, there is the possibility of viewing a quantitative ordering of local and regional dominance, but we would emphasize qualitative differences. For example, Los Angeles is obviously important today as a regional center in the West; but the metropolitan area has been described as "twenty-four suburbs in search of a city" (Smith, 1968: 252).

Methods and Procedures

The bulk of the data reported in this study are taken from a sample of 70 U.S. cities in 1890. To assess a theoretical perspective such as that presented in this paper, virtually any time period could be utilized. This paper is part of a larger project examining urbanization in the U.S. and this historical examination requires

data from an early phase of large-scale urbanization in the U.S. Prior to 1890, it was not possible to locate much of the required data relating to intercity postal and railroad service, church hierarchies, banking, etc. Even though a Census Bureau fire in 1921 destroyed portions of the 1890 census, it was the earliest time for which many potential indicators of dominance were available. When data are presented in this paper for later time periods, the same 70 cities provide the sample.

We began with a list of 81 cities, selected to be representative of both different regions in the country and varying city-size categories. A few of the selected cities eventually had to be excluded because they could not be placed into any region. In every case, these were demographically smaller cities, such as Peoria, Illinois. Extensive missing data later forced the removal of a few additional cities, and they too tended to be smaller in population size. Thus, the final sample of 70 cities slightly underrepresents smaller cities, though they are not absent from the sample. (A complete listing of sampled cities is included in Table 2.) In 1890, the sample is almost identical to the universe of (then) demographically major cities. It includes about three-fourths of that universe in 1970.

Initially, we attempted to construct regions utilizing criteria that would be relatively invariant over time: geographical land-use and Federal Reserve Districts. The immediate problem was that these two criteria did not produce congruent regions and we had no rationale for favoring either when they disagreed. A new criterion, transportation-communication patterns, was subsequently utilized as the final arbiter of regional boundaries. This specifically involved the number of railroad mail routes run weekly between all towns and cities in the U.S. (U.S. Postmaster General, 1890). Because passengers were also carried on these trains, the railroad mail routes simultaneously indicated patterns of transportation and communication.

Utilizing this criterion, any city with less than 50 percent of its total routes connecting with other cities in the proposed

region was excluded from that region. It was placed into another, when possible. Some cities, however, could not be placed into any region in 1890. Peoria, Illinois, for example, connected partially with the Midwest, partially with the Ohio Valley and, to a lesser extent, with the South. But 50 percent or more of the city's routes were not in any one region. By contrast, larger cities—such as Buffalo and Louisville—that provided points of connection between regions could be placed without exception into a single region.

It must be recognized that the exact boundaries of any geographical unit are difficult to specify precisely (cf. Gibbs, 1961). Further, the exact boundaries of regions in the U.S. have been shown to vary according to the criteria that are utilized (Green, 1955: 283–300). In the final analysis, therefore, they are arbitrary. There are two justifications for the regional boundaries utilized in this study. The first is procedural, namely, their construction in accordance with transportation and communication routes. Especially from an ecological perspective (Hawley, 1950; 1971), they provide a more relevant criterion than others that have been used often (e.g., geographic land use). Second, the regions as developed here correspond well with the regional boundaries typically described in historical research (cf. Sutter, 1973).

For the 70 cities in the nine regions, a large number of potential indicators of the three types of dominance were selected from varied sources. The items include conventional financial-commercial indicators (e.g., the dollar value of clearing-house exchanges), plus items that potentially relate to a city's intellectual role (e.g., scientific journals published), its role in relating the U.S. to other nations (e.g., import duties collected), the kinds of organizations located in the city (e.g., headquarters of national trade unions), etc. The final list of potential indicators was limited to about 20, however, because when the ratio of cases (i.e., cities) to observations (i.e., variables) exceeded about three and one-half to one, the factor solution was confounded by high collinearity in the correlation matrix (cf. Harmon, 1967). The 20 variables finally

included were selected for their theoretical potential as indicators of one of the three types of dominance, and an approximately equal number of indicators were selected for each type of dominance.

The variables were subjected both to orthogonal and oblique factor solutions which produced only very minor fluctuations in defined factors (cf. Abrahamson and Johnson, 1974: 521–32). In most cases, the orthogonal factors were retained for subsequent analysis. We hypothesized that the variables would sort into three factors associated with national-international, regional and local dominance. City scores on these three factors then would be utilized to test a number of more specific hypotheses.

At this point, however, two of the "methodological foibles" inherent to factor analysis must be noted. First, we recognize that our substantive labeling of these factors is a subjective process. Others might wish to argue with the labels we will apply, though we believe the offered interpretations to be theoretically well justified. Second, because factor analysis is essentially a data reduction technique, the factors that are obtained are totally dependent upon the mix of variables that are initially included. Therefore, despite our efforts to balance variables by type, we consider it inappropriate to interpret eigenvalues, or any other property of the factors, as indicating the strength or importance "in reality" of any factor (cf. Rees, 1971: 220–33). Thus, we are not proposing that factor analytic results alone show the three types of dominance to exist as separate types. Rather, we view the factor analysis primarily as a means for developing multiple item measures of each type of dominance to be used in subsequent analyses.

Results

The factor solutions resulted in a number of factors, three of which could be substantively associated with the three types of dominance previously discussed, i.e., national-international, regional and local. This portion of the results is presented in Table 1. Reading diagonally across the table, the boxed-in factor load-

ings indicate the items (from the left margin) that identify the substantive factors (presented across the top of the table).

National Dominance

Inspection of the items that load highly on the national dominance factor reflect both the national and international aspects of this dimension. However, subsequent examination of cities' factor scores on this orthogonal factor disclosed that a number

of small and otherwise "unimportant" cities with ports linking to Canada had very high scores—Port Huron, Michigan, for example. In the oblique solutions though, there was a more pronounced distinction between the national and international aspects of the dimension (see the last two columns in Table 1). In the oblique national factor, the two explicitly international items (international passengers and import duties) have the weakest load-

Note: Where appropriate, items converted to per capita figures. All variables standardized prior to factor analysis.

ings among the defining items. By contrast, they have the strongest loadings on the oblique international factor.

Because this study focuses solely upon the U.S., we decided to de-emphasize the international aspect and utilize the oblique national factor as the measure of national dominance. (This oblique factor correlates only weakly with the orthogonal measures of regional and local dominance. The correlations are .29 and .27, respectively.)

Table 2 presents the standardized factor scores of all 70 cities on national dominance (oblique factor) in 1890. As would be expected, the highest scoring cities—in fact, the three highest—are located on the East Coast. The West Coast, by contrast, contains three of the five lowest scoring cities. More than location though, national dominance would be expected to correlate

with population size (Bogue, 1949; Duncan et al., 1960; Carroll, 1963: 166–173).

In order to assess the correlates of all types of dominance more completely, we selected a large number of variables relating to the characteristics of cities and their populations and, again using factor analysis, constructed potential (composite variable) correlates. The items that define each correlate (i.e., factor) are presented under the summary of results in each appropriate table. A multiple correlation analysis, with respect to national dominance, showed size-density to be the strongest independent correlate, followed closely by ethnic social organization and then by labor force modernization. These three variables alone are able to explain almost three-quarters of the variation in national dominance.

Table 3. Correlates of National Dominance

Major Independent Variables	Beta	
Size-Density	.44	Total Multiple R=.88
Ethnic Social Organization	.40	Multiple R ² =.77
Labor Force Modernization	.24	(R ² of major variables=.71)

Items and Factor Loadings by Correlate					
Size-Density		Ethnic Social Organization		Labor Force Modernization	
Population Density	.84	Foreign Lang. Newspapers	.92	% Professional	.95
Street lamps/Mi.	.84	% Foreign Born	.43	% in Trade & Transp.	.95
Population Size	.83	Pop. Increase, 1880-90	-.25	% of Women	.92

It seems clear that the most nationally dominant cities in 1890 were large, established cities that had already received large numbers of immigrants prior to 1890 and whose labor force composition already was reflecting the growing urbanization and industrialization of the U.S. The highest scoring cities—New York, Boston and Philadelphia—are excellent examples of such large, “modern,” point-of-entry cities.

Regional Dominance

The regional dominance factor, presented in Table 1, is composed of two kinds of items. The first entails communication and transportation involving U.S. mail and train passengers. These items suggest a picture of regions as geographical areas based upon transportation and communication, the same criterion used elsewhere in this study to establish regional boundaries. The second type of item involves regional and district organizations. The Catholic Church hierarchy is the only religious group presented here, but the Episcopalian Church had an almost identical loading on the regional dominance factor. It was eliminated from the final analysis because of the previously discussed need to maximize the cases-to-observations ratio.

Table 4 presents the standardized factor scores of all cities on regional dominance, according to region. Here we made the assumption that the regional dominance factor reflected the degree of influence exerted by a city within the boundaries of the regions as indicated by the railroad mail routes. However, it must be recalled

that regional boundaries, no matter how constructed, are tentative and approximate. In this case, our assumption that regional dominance, as measured by that factor, operates within the confines of the railroad-determined regions must be considered especially tentative and approximate.

Because these regional dominance scores are standardized for the entire sample, it is possible not only to rank cities within regions, but to make comparisons across regions. Thus, it may be inferred, for example, that San Francisco was a more dominant city in the Pacific region than New Orleans was in the Southern region. This means that San Francisco was more of a locus for regional and district organizations, and a more important hub of regional transportation and communication.

In contrast to national dominance, where the correlates were able to explain an unusually high percentage of the total variation, their capacity to explain regional dominance is more moderate (multiple R² = .34). The strongest independent correlate is distance from a city high in national dominance (beta = .54). Distance involved railroad mileage between each city and one of the eight highest scoring cities on national dominance. Thus, again resembling prior findings, it appears that the regional dominance of cities was hindered by proximity to cities high in national dominance (Carroll, 1963:166-73). The other major correlates were the same as for national dominance: labor force modernization (beta = .43) and ethnic social organization (beta = .20). However, size-density—the major correlate of na-

tional dominance—was unrelated to regional dominance.

The difference in major correlates further supports the argument that national and regional dominance should be conceptually differentiated. However, the strongest case for their separation results from an examination of the geographical distribution of nationally and regionally dominant cities. It suggests that integration in 1890 followed two very different

functional and geographical patterns. In approximately one-half of the regions, a nationally dominant city also functioned as the primary regional integrator. This pattern characterized the South, North-central, Rocky Mountain and Pacific regions. In each of these regions, the dually dominant city tended to be in a central location geographically, either in the ecological center of the region (e.g., Denver in the Rocky Mountain region) or, as

illustrated by San Francisco, had a central coastline position with respect to other cities in the region (cf. Gibson, 1973). A similar pattern characterized the Southwest which contained a (weak) regional integrator, El Paso, but no nationally dominant city.

In the remaining regions, a regionally dominant city was not nationally dominant and these regionally dominant cities tended to be located at the corners, rather than centers of their regions. This pattern characterized New England, East, Ohio Valley and Midwest. The corner positions of these regionally dominant cities probably provided connectivity for the entire region to other regions or to Canada. By contrast, the center location of the dually dominant cities suggests that they may have provided greater integration and less connectivity for their regions. This supposition is supported by the data which indicate that the two different patterns were associated with markedly different degrees of regional integration. In the four regions where the regionally dominant city was not also nationally dominant, the mean score of the regionally dominant city on regional integration was only .77—less than a standard deviation from the mean of all cities. By contrast, in the four regions where national and regional integration coincided in the same city, the mean regional dominance score of the regionally dominant city was *very* high, specifically, 2.58.

Finally, these two patterns are associated, though not strongly, with different degrees of "maturity," or economic development. Per capita bank assets, for example, were higher in 1890 in those regions where national and regional dominance were exerted by different cities. A comparison of bank asset means shows values of .47 per capita in the differentiated dominance regions compared to .38 in the regions where national and regional dominance were exerted by the same city. This suggests an interpretation analogous to that hypothesized for entire nations by Berry (1961: 573–8), namely, that development is associated with the movement from a primate city to a hierarchical pattern of city dominance. However, Berry reports numerous exceptions

to this pattern at a national level of analysis, and this is also characteristic of our findings at the regional level. Thus, while differences in mean banking assets indicate that the differentiation of regionally and nationally dominant cities is associated with development, the pattern is not without significant exceptions. For example, in the Pacific region where San Francisco played the dual role, per capita banking assets were second highest in the nation.

Local Dominance

Local dominance, like regional dominance, primarily is composed of items relating to transportation and communication (see Table 1). Some of the same items load on both factors, probably reflecting the way in which metropolitan areas blended into extended hinterlands, especially in 1890. However, the clear difference between the two lies in the types of transportation and communication involved—short distance for local dominance and long distance for regional dominance. It also should be recalled that these factors are orthogonal, hence, unrelated to each other.

What stands out strongly from an examination of the distribution of local dominance scores, presented in Table 5, is the relative absence of variability. To illustrate, over two-thirds of all cities had local dominance scores which were less than one-half of a standard deviation above or below mean.

This tendency for most cities to score weakly on local dominance is probably due to the fact that there was no mode of transportation available in 1890 that compared in efficacy to the inter-city connections provided by the railroad. There was daily commuter train service to several of the larger cities, but it was expensive; horse-drawn vehicles and bicycles, the major alternatives, were impractical. Thus, cities generally lacked the transportation mode by which to integrate a metropolitan area.

Given the truncated variability of local dominance, it is not surprising that the correlates were least able to account for variation in it; the multiple $R = .35$ ($R^2 =$

Table 5. Local Dominance in 1890

.12). The strongest independent correlate was size-density ($\beta = -.44$), indicating that while few cities effectively integrated their surrounding areas in 1890, the largest and most densely populated cities fared still worse. The only other substantial correlate of local dominance was ethnic social organization ($\beta = .38$). This may indicate that the "pull" of ethnic bonds operated as one of the few integrative metropolitan area forces. The relative invariance of local dominance and the corresponding inability to account for substantial variations in local dominance make further speculation unwarranted. However, note that of the four most locally dominant cities in 1890, all except Pittsburgh had extensive political unification with their metropolitan areas by 1970.

This ranged from the integration of specific functions (San Francisco and the Bay Area Authority) to complete consolidation (Jacksonville and DuVal County). Thus, local dominance appears to display considerable historical continuity. Pittsburgh is an exception, but its very high local dominance was probably due to the large adjoining population of Allegheny City which became part of Pittsburgh shortly after 1890.

Historical Changes

Changes in the U.S. as an urban system suggest that some changes in the nature of urban dominance, especially at the local level, must have occurred correspondingly. Developments in transporta-

tion and communication, for example, undoubtedly have increased local spheres of influence and modified relationships among nearby cities (Hawley, 1971). However, historical analyses of what we have termed national and regional dominance suggest that there has been substantial continuity over time; that is, cities' dominance locations at the turn of this century appear to have changed little in ensuing years (Duncan and Lieberman, 1970). The capacity of various measures to reflect that continuity over time, therefore, can provide an additional criterion for evaluation of the measures themselves.

This assessment requires that the measures of dominance used for 1890 be pitted against each other in terms of their ability to predict future states of cities. The most critical test involves a comparison between a measure of multifaceted dominance and a conventional fiscal or economic measure. The former is readily available in the form of the national dominance factor. Our 1890 fiscal measure is the volume of Federal Reserve Bank drafts. The Federal Reserve Banks have been a widely used indicator of (national) dominance when the financial aspects of dominance were stressed. Their utilization was initially suggested by Gras (1922) and they were used shortly afterward as the criterion of metropolitan status by Park and Newcomb (1933). This early use simply differentiated between major urban centers and all others according to the presence or absence of Federal Reserve Banks. More variation was later built into the measure by focusing upon the monetary value of bank drafts drawn on Federal Reserve Banks outside the city's Federal Reserve District. Cities are then more

elaborately differentiated as (nationally) dominant cities according to this volume of banking activity (Duncan et al., 1960).

Our first dependent variable is the number of voluntary organization headquarters located in a city in 1970. If such primarily nonfiscal aspects of cities are derived largely from the fiscal structure, then city scores on voluntary organizations in 1970 should correlate about equally well with either fiscal dominance in 1890 (Federal Reserve banking) or multifaceted dominance in 1890 (the national dominance factor). The relationships, presented in Table 6, show that the multifaceted dominance factor provides unambiguously better prediction.

However, it might also be argued that if national dominance is primarily a fiscal phenomenon, then the historical predictability of nonfiscal considerations (such as voluntary organizations) is not highly relevant. Therefore, to offer a more critical test, we examine Federal Reserve activity itself in 1970. The 1890 (independent) variables remain the same. These results are also presented in Table 6.

The differences in predictability are equally large whether the dependent variable is fiscal or nonfiscal. In both cases, relationships with the multifaceted dominance factor are substantially higher. Therefore, we suggest that if dominance is to be viewed as reflecting an enduring structural arrangement, that structure is best conceived as fiscal, intellectual, cultural and organizational, rather than fiscal alone.

AGE, FERTILITY EXPECTATIONS AND PLANS FOR EMPLOYMENT *

ROSS M. STOLZENBERG

LINDA J. WAITE

University of Illinois, Urbana-Champaign

American Sociological Review 1977, Vol. 42 (October):769-783

Fertility, female labor force participation, and the relationship between them are key subjects in a number of theoretical and applied areas of sociology. Because sex role norms and the widespread use of birth control devices have given American women much control over their fertility and substantial choice in their labor force activity (or inactivity), understanding the development and interrelationship of labor force participation plans and fertility expectations assumes great importance in understanding actual labor force participation and actual fertility. As a step toward understanding this development, we describe and attempt to explain the effect of women's age on the relationship between their labor force participation plans and their fertility expectations. Using data from a national sample of young women aged 19 to 29 in 1973 (N=3,589), we find a strong, linear relationship ($r=-.96$) between women's age and the effect of their plans for labor force participation on the number of children that they expect to bear in their lifetime. An explanation of this finding (called the Learning Hypothesis) is advanced which survives tests against several plausible alternative hypotheses. Policy implications and productive paths for future research are discussed.

This paper reports an investigation of the effects of a woman's age on the relationship between the number of children she expects to bear in her lifetime and her long-term plans for labor force participation. The motivation to study women's plans for childbearing and paid employment comes from observing that American women now exert a great deal of control over both their fertility and their labor force participation (see Bowen and Finegan, 1969; Sweet, 1973; Ridley, 1958; Bumpass and Westoff, 1970). If women control their fertility and labor force participation, then understanding the relationship between their plans for paid employment and their plans for childbearing is a prerequisite to understanding their actual fertility and labor force activity.

Our motivation to study the effects of a woman's age on the relationship between the number of children she expects to bear and her long-range plans for labor force participation comes from two sources, one theoretical and the other policy-oriented. On the theoretical side, it is clear

that an adequate understanding of the relationship between labor force participation plans and fertility expectations must include knowledge of the etiology of that relationship. Several past studies have laid great stress on the time at which fertility and employment plans become linked, and certain analysts have argued that the timing of events in a woman's life prior to childbearing has important consequences for the development of her tastes for employment and motherhood (e.g., Lipman-Blumen, 1972; Rossi, 1968; Presser, 1971; Bumpass, 1969). Tien (1967) and Willis (1973) have argued that labor force participation plans and fertility expectations are not established until marriage; and Blake (1969) presents data which suggest that, by the end of high school, girls have already developed inter-related tastes and long-range plans for employment and fertility. For the moment, conflicts between Blake, Tien and others are not critical. Rather, the points to be culled from these studies are that temporal aspects of the development of the relationship between labor force participation plans and fertility expectations have been widely recognized as theoretically important and, to the best of our knowledge, there is no rigorous empirical analysis of the effects of women's age on this rela-

* Thanks for many useful comments to members of the ASA Sex Stratification Seminar and Larry Suter. This research was sponsored by the U.S. Department of Labor under agreement A-20-11-24-15; opinions expressed herein are not necessarily those of the Department of Labor.

tionship. This paper is written to help fill this gap.

Our second motivation to study the effect of women's age on the relationship between their labor force participation plans and fertility expectations derives from recent proposals to manipulate the birth rate in industrialized countries by motivating more women to plan active labor force participation throughout adulthood (see Blake, 1969; Davis, 1967; Hoffman and Nye, 1974). These fertility reduction schemes would seem to offer a technology for lowering fertility even in nations where effective birth control is already widely used, since they operate by altering women's motivation to bear children rather than their ability to avoid doing so. However, the efficacy of this strategy depends entirely on a strong negative effect of labor force participation plans on the fertility expectations of women who are *in the prime childbearing years*. Thus, for example, if a substantial inverse effect of labor force participation plans on fertility expectations does not develop until women are, say, 25 years old, then women who start their childbearing before they are 25 would have only limited ability to reduce fertility to accommodate labor force participation plans (though their work plans might make them regret their earlier fertility). So, the research reported here is also offered as a modest step toward evaluating some hard-nosed suggestions for implementing population policy.

Before reporting our findings, we review existing literature on which our research builds and derive the key hypothesis tested in our empirical analysis. Then we give a brief description of our data and statistical methods. And, finally, we report our findings and discuss their implications.

A Hypothesis about the Effects of Age on the Relationship between Labor Force Participation Plans and Fertility Expectations

That employment and childrearing are competing activities is demonstrated by the wide variety of conditions under which they are negatively related. Women

who have large families are less likely at any point to be in the labor force and tend to have worked a smaller proportion of their lives than women with fewer children (Sweet, 1973; Kupinsky, 1971; Mason, 1974). Employed women usually have smaller family-size expectations and ideals than their non-employed counterparts (Pratt and Whelpton, 1956; Ridley, 1958); and females who plan to be working at some time in the future plan to have fewer children than women with no such intentions to work (Whelpton et al., 1966; Ryder and Westoff, 1971).

More recent data suggest the same pattern. In 1974, 30 percent of the married, husband-present 25- to 34-year-old mothers with children under three years of age were in the labor force; in that same year, 78 percent of the childless husband-present married women in that same age group were labor force participants (U.S. Department of Labor, 1975:62).

The sheer difficulty of combining the roles of employee and mother suggests reasons for the strong, negative association between childbearing and labor force participation. Employed mothers must arrange and pay for child care during the hours that they are on the job and, upon returning home from work, they tend to find themselves with a full complement of household duties (see Vanek, 1974). Thus, for the woman who wants or merely expects to be employed after childbearing, limiting fertility offers an obvious rational strategy for coping with the combined demands of childrearing and employment.

While limitation of fertility can serve as a strategy for minimizing the workload of women who plan to be employed after childbearing, recent research on women's careers also suggests that fertility limitation may serve as a rational strategy for maximizing the quality of a woman's post-childbearing employment. That is, when a woman interrupts her labor force participation in order to bear and raise children (and most women still do), the skills and knowledge she uses on the job tend to become obsolete and/or forgotten through disuse. As skills and knowledge (her human capital) depreciate, the woman becomes less valuable to employ-

ers; and the wages she can earn and, possibly, other desirable features of the jobs she can command deteriorate (Ross, 1973; Mincer and Polachek, 1974). But the fewer children a woman bears, the less time she must take out of the labor force to raise her children to an age where they can be left to the care of others while the mother is at work, other things being equal. Thus, a woman who plans to be employed after childbearing might rationally plan to limit her childrearing-related interruptions in labor force participation by limiting the number of children she bears, and thereby minimize the extent to which this childbearing-related interruption degrades the quality of her employment after childbearing.

Although limiting fertility might serve as a rational strategy for women to reduce the adverse effects of their child care duties on the quality of their employment following childbearing, women are likely to follow such a strategy only to the extent to which they are aware of the deleterious effect of labor force participation interruptions on the quality of post-interruption employment. Accurate information about wages, the availability of jobs and other market conditions is known to be unevenly distributed, and many workers do not have the information necessary to make optimal work-related decisions (Gordon, 1972; McCall, 1970; Rees and Shultz, 1970). Building on these findings, we speculate that women learn about the labor market as they age, and that their information about the effects of interruptions in labor force participation improves as they pass through their late teens and twenties. We suggest that as women grow older, they increasingly realize that their satisfactions from future employment are likely to improve if they limit the number of children they plan to bear. That is, women become increasingly aware that (1) their childcare responsibilities will cause them to interrupt their labor force participation, (2) employment interruptions reduce their employability and wage potential and (3) that they can reduce the length of their child-care-related employment hiatus by reducing the number of children that they bear. Thus, we hypothesize that the effect of women's labor

force participation plans on their fertility expectations becomes increasingly negative as they age. We call this hypothesis the Learning Hypothesis, and the remainder of this paper is devoted to evaluating its worth as an explanation of the effect of women's age on the relationship between their labor force participation plans and fertility expectations.

Data and Method

Our strategy is to estimate the parameters of a model of labor force participation plans and fertility expectations separately for women in each of several different age groups. Once these parameters are estimated, age-related changes in the effects of labor force participation plans on fertility expectations can be ascertained by examining age-group differences in the relevant parameters of the model. A model which is appropriate for this strategy should have two properties which are worth mentioning in some detail at this point. First, the model should allow for the complex relationship between labor force participation plans and fertility expectations. The empirical and theoretical work of some researchers suggests or implies that fertility plans affect labor force participation plans. (Sweet, 1973; Tien, 1967; Bowen and Finegan, 1969; Cohen et al., 1970).¹ Other work suggests or implies that labor force participation exerts a negative effect on the number of children that women want, expect, consider ideal, or actually have (Pratt and Whelpton, 1956; Ridley, 1958; Whelpton et al., 1966; Kupinsky, 1971; Mason, 1974). Perhaps the most sophisticated works on the subject are those that suggest that women's preferences for employment and childbearing *both* affect each other (Blake, 1970; Terry, 1974). Waite and Stolzenberg (1976) estimate a model which allows (but does not require) causality to run in either or both directions between labor force participation plans and fertility expectations. They found evidence of reciprocal effects, though the

¹ Our statement about the implications of this work depends upon the assumption that fertility and labor force participation are not completely unplanned activities.

impact of labor force participation plans on fertility expectations was much greater than the effect running in the opposite direction.

A second important methodological point is that past theory and empirical research strongly suggest that women's plans for both fertility and labor force participation are related to a number of their background characteristics such as race, educational attainment, and marital status. Thus, we include some of these background characteristics in our statistical models, lest we mistake the effects of a neglected background factor which causes both work and fertility plans for a relationship between these variables.

The model of labor force participation plans and fertility expectations which was developed by Waite and Stolzenberg (1976) satisfies the two methodological requirements just mentioned; it allows (but does not require) one-way or reciprocal causation between women's plans for future labor force participation and expected family size and it includes, as common antecedents of both fertility expectations and labor force participation plans, several variables which have been shown to affect both work plans and childbearing expectations. We will use this model in the present analysis. We will also use the same data base that we employed in the earlier analysis (Waite and Stolzenberg, 1976).

Since the Waite-Stolzenberg model and the data used to estimate it were described in detail earlier in this *Review*, only brief descriptions are needed here. Data are drawn from the National Longitudinal Survey of Labor Market Experiences of Young Women (NLS) done by the U.S. Bureau of the Census and the Ohio State University. The sample started in 1968 with about 5,000 women who were then representative of U.S. females aged 14 to 24 years. By 1973, about 86 percent of the original sample was intact. After eliminating cases with missing data, we were left with an N of 3,589. Variables used in the model are described briefly below and more extensively in Waite and Stolzenberg (1976):

LFPP, or work plans, is a measure of the respondent's plans for labor force

participation at age 35. This variable equals one if the young woman plans to be employed, zero if she is not sure or plans to be out of the labor force.

FE, fertility expectations, is the total number of children which the respondent plans to have in her lifetime.

SIBS is the number of siblings the respondent had in 1968.

IFS, ideal family size, equals the number of children that the respondent considers "ideal" for a family.

BLACK, a dummy variable for the young woman's race, equals one if she is black, zero otherwise.

ED equals the number of years of schooling completed by the respondent.

MSP is a dummy variable for marital status which equals one if the young woman is married and living with her husband, zero otherwise.

AGE equals the respondent's age in years at the time of the 1973 interview.

LEPMOM, the labor force participation of the respondent's mother when the respondent was 14 years old, equals one if the mother worked, zero otherwise.

WORKATT, work attitudes, is a nine-item scale of the young woman's beliefs about the costs and benefits of labor force participation by married women.

All correlations, means and standard deviations used in the present paper are reported in Suter et al. (1975).

The Waite-Stolzenberg model is presented pictorially in Figure 1 and mathematically in the two equations under the path diagram. For present purposes, the key feature of the model is that it allows, but does not require labor force participation plans and fertility expectations to affect each other. These effects are, of course, "net" of the effects of variables on the left side of the diagram (corresponding to the right sides of the equations).² Parameters of the model are estimated by two-stage least squares.

² The Waite-Stolzenberg model does not allow a *direct* effect of work attitudes on fertility but it does allow an indirect effect through labor force participa-

$$\widehat{FE} = c_0 + c_1 \text{AGE} + c_2 \text{MSP} + c_3 \text{ED} + c_4 \text{BLACK} + c_5 \text{IFS} + c_6 \text{SIBS} + c_7 \text{LFPF}$$

Figure 1. A Basic Model of Labor Force Participation Plans and Fertility Expectations

We feel obliged at this point to reiterate a commonly misunderstood point: the nonrecursive model used in this analysis *allows* work plans and fertility expectations, both measured in the same survey, to influence each other. However, this model also allows one-way causation or no causal influence between the two at all. The presence of simultaneity is, in some sense, an empirical question, and we do not force it to appear in our model.

Age and the Relationship between Labor Force Participation Plans and Fertility Expectations

In order to investigate the effects of a woman's age on the relationship between

tion plans. This restriction is necessary to allow estimation of coefficients of causal variables. Rather than contradicting students of fertility, such as Rertert and Bumpass (1974) and Scanzoni (1975), who have argued that sex role attitudes and desired fertility are related, we are building on their work by specifying a mechanism by which attitudes toward female employment are related to the number of children that women plan to bear. In calculations not reported here, we obtained further support for our use of WORKATT in the Basic Model by showing that substituting a different variable in its place produced only the most trivial changes in the estimated effect of LFPP on IFS. This result is the sort of thing that one hopes for when using two-stage least squares—changing the instrumental variables does not alter the all-important relationship between the endogenous variables. Further, we have found that IFS can be deleted from the Basic Model without producing changes in the conclusions reported in Waite and Stolzenberg (1976). However, deleting IFS reduces the efficiency of the instruments and, thus, greatly increases the instability of the estimates. Therefore, we find it prudent to leave IFS in the model. And, finally, we can bring one new piece of evidence to bear in support of our decision to exclude WORKATT from the equation for FE. Following Kohn and Schooler (1973, who follow Duncan et al., 1968), we calculated the residuals of the two equations in the Basic Model and then correlated these residuals with the exogenous variables. If our assumptions are correct regarding the exclusion of WORKATT from the equation for FE, then the correlation between WORKATT and the residuals from the equation for FE will be zero. The actual correlation between WORKATT and the residuals is $-.0088$, which seems sufficiently small to be regarded as no different from zero. Correlating WORKATT with the residuals is a weak test of our assumptions but, taken together with our substantive arguments and other empirical results, we believe that it completes a solid case in support of our decision to exclude WORKATT from the equation for fertility expectations.

her fertility expectations and labor force participation plans, we estimated the parameters of our Basic Model separately for women in five age categories: 19 to 20 years old, 21 and 22, 23 and 24, 25 and 26, and 27 to 29 years of age. The complete results of these regression equations are provided for reference in Suter et al. (1975). However, inasmuch as these regressions provided some 70 metric coefficients, 70 standardized coefficients, 70 standard errors, and 10 R-squared statistics, our discussion of these results will be facilitated by using less detailed tables in this article. Table 1 presents the metric coefficients for work plans in the equation for fertility expectations by respondent's age. Note that the coefficients for work plans are all negative and that they increase in absolute value strictly monotonically as age increases. Two features of these results are striking. First, the difference between the coefficient for 19- and 20-year-olds and the coefficient for 27-through 29-year-olds is substantial. For the youngest group, the coefficient is about $-.28$, indicating that when the effects of other variables in the Basic Model are held constant, women's plans to participate in the labor force at age 35 decrease their expected family size by an average of .28 children. For the oldest age group, the coefficient for work plans is about -1.44 more than five times as large as the effect of work plans on the youngest group. Thus, for 27–29-year-old women, plans to participate in the labor force at age 35 decrease expected family size by an average of 1.44 children, net of other factors included in the equation for fertility expectations. Inasmuch as the 27–29-year-old women in the NLS sample expected to bear an average of 2.5 children in their lifetime, the estimated effect of work plans on the expected fertility of these women reasonably can be regarded as enormous.

The second striking feature of Table 1 is the linearity of the relationship between women's age and the metric coefficient for work plans. Space limitations do not allow graphic presentation of this relationship, so we use the Pearsonian correlation to measure the degree of linear association between age and the effect of LFPP on

Table 1. Net Effects of Labor Force Participation Plans (LFPP) on Fertility Expectation (FE), by Age Group, with Corresponding Multiple R-Squared Statistics

Age Group	Partial Regression Coefficients		R ² for Equation	N
	Metric (Unstandardized) Coefficients	Beta (Standardized) Coefficients		
19-20	-.278 (.422)	-.111 (.168)	.430	663
21-22	-.646 (.290)	-.292 (.131)	.273	739
23-24	-.691 (.413)	-.308 (.184)	.295	682
25-26	-.804 (.475)	-.351 (.207)	.123	686
27-29	-1.439 (.627)	-.540 (.235)	.037	819

FE. The zero-order correlation between the midpoints of the age groups and the coefficients for work plans is $-.955$ and is significantly different from zero at the 2.5 percent level ($F = 30.75$). Thus, age explains 91.1 percent ($= [-.955]^2$) of the variance in the coefficient for work plans. We fitted a straight line to the metric coefficients reported in Table 1 by least-squares regression,³ obtaining the following parameter estimates (where b is the coefficient of work plans):

$$\hat{b} = 1.963 - 0.1154 \text{ Age } R^2 = .9111. \quad (1)$$

According to equation (1), the effect of work plans on fertility expectations changes by $-.1154$ expected children per year of age.

³ The coefficients of work plans in the different age groups have different standard errors. Thus, the ordinary least-squares assumption of homoscedasticity is violated in our estimation of the parameters of equation (1). This problem can be overcome by using the inverses of the squared standard errors of the coefficients for work plans as estimates of the main diagonal of the variance-covariance matrix of the residuals in a generalized least-squares (GLS) regression of b on age. Since the coefficients for work plans were estimated from disjoint subsets of the NLS sample, the off-diagonal elements of the variance-covariance matrix of the residuals are all zero. Following this procedure we obtain the following GLS regression of b on Age:

$$b = 1.6666 - .1033 \text{ Age } R^2 = .862. \quad (1a)$$

The F statistic for the GLS regression is 18.66, indicating that the hypothesis of "no relationship" between age and the coefficient for work plans can be rejected at the 2.5 percent significance level.

We have also derived an alternative method for estimating the relationship between age and the effect of LFPP on FE. The alternative method produces nearly identical estimates of the relationship between age and the effect of LFPP on FE, increasing our confidence in the estimates presented in equations (1) and (1a). These calculations are presented in Stolzenberg and Waite (1976).

Thus, our empirical findings are consistent with the Learning Hypothesis presented at the start of this paper. We now consider (and reject on empirical grounds) some alternatives to the Learning Hypothesis which are also consistent with the empirical results which we have just presented.

Testing Alternative Hypotheses

According to the Learning Hypothesis, as women grow older, they tend increasingly to realize that the rewards of their post-childbearing employment are likely to be greater if they have a small rather than a large family. Thus, as women age, the inhibiting effect of their labor force participation plans on their fertility expectations becomes stronger. Unfortunately, the NLS surveys of young women do not contain questions designed to determine young women's ideas about the effects of labor force participation interruptions on their employability and earning power. Thus, it is not possible to test all parts of the Learning Hypothesis. However, we

can provide some indirect support for our reasoning by showing that certain plausible alternative explanations of our findings are *not* true. We will consider two of these alternatives. First, we examine the possibility that our findings are caused by cohort differences in sex-role attitudes rather than age differences in knowledge of factors affecting employability and earning power. Second, we will address the possibility that we are mistaking the effects of women's life cycle stage for the effects of their age on the relationship between work plans and fertility expectations, thereby providing an erroneous interpretation of our findings.

For convenience, we will call the first alternative hypothesis the Liberation Hypothesis. According to this hypothesis, there has been a secular trend in women's ideas about proper role behavior for mothers of young children. As a result of this trend, it is more acceptable to members of recent birth cohorts than to those of less recent birth cohorts for a mother of young children to spend considerable time away from home in order to hold employment, assuming that responsible adult care is provided for the children in the mother's absence. Thus, according to the Liberation Hypothesis, women from younger cohorts who expect to be employed after childbearing expect to interrupt their labor force participation for less time per child than women from older cohorts who have similar expectations of labor force activity. As a result, members of younger cohorts find childbearing less detrimental to their future employability and earning power than women from older cohorts, and maximizing earnings and employability is less reason for members of younger cohorts to limit their fertility than for women from older cohorts. Because the data we utilize in this paper are cross-sectional, cohorts are indistinguishable from age groups. Therefore, if the Liberation Hypothesis is true, the relationship we find between age and the effect of work plans on fertility expectations is partially or even entirely the effect of cohort differences in sex-role attitudes, not developmental factors which have caused age differences in knowledge of

the effects of interruptions in labor force participation.⁴

Fortunately, the NLS data permit us to investigate the possibility that age differences in sex-role attitudes account for the relationship we have found between women's age and the effect of the labor force participation plans on their fertility expectations. The Liberation Hypothesis assumes that younger women are more liberal than older women in their sex-role attitudes and more tolerant of work outside the home by mothers of young children. Our data include four Likert-scale questions which deal with the effects of women's employment on the welfare of their families. These are items 1, 4, 6 and 8 in the work attitude scale, WORKATT, mentioned earlier and discussed in detail in Waite and Stolzenberg (1976). These items are presented in Table 2. The correlation between responses to these items and women's age are given in the right-most column of Table 2. Although the first and sixth items have correlations with age which are significantly different from zero at the one percent level, it is clear that none of these items has a strong enough association with age to account fully for the powerful relationship between age and the effect of labor force participation plans on fertility expectations. (Means and standard deviations of responses to these items for the age groups showed no non-linear associations.) A more rigorous test of the Liberation Hypothesis is available using multiple regression. Since the Liberation Hypothesis states that the rela-

⁴ One reader of this paper suggested that the effect of age on the relationship between work plans and fertility expectations might be due to cohort changes in number of children expected, with older women anticipating substantially larger completed families than their younger counterparts. One also might argue that younger women should be more likely to plan for later labor force participation than should older women. However, neither of these arguments holds up under close inspection. The zero-order correlation between Age and FE is .0364. The means and standard deviations of fertility expectations are very similar for all age groups, differing by only 0.10 child between the oldest and the youngest (2.52 versus 2.41). Also, approximately the same proportion in all age groups plan to work at age 35; .44 for those 19 and 20 versus .49 for those 27 to 29. The correlation between Age and LFPP is -.0140.

tionship between a woman's age and the effect of her work plans on her fertility intentions is due to cohort differences in sex-role attitudes, the hypothesis will be supported if the relationship between age and the coefficient for work plans in the equation for fertility expectations vanishes when the effect of these attitudes is held constant. In order to test the Liberation Hypothesis, we have computed several regression analyses which are reported in columns A and B of Table 2. In each regression, we allow the *coefficient* for work plans in the Basic Model to be caused by two independent variables: the midpoint of the age span of the women for whom the coefficient was estimated, and these women's mean value on a Likert-scale questionnaire item which measures attitudes about the effects of a mother's employment on the welfare of her family.⁵ The Learning Hypothesis predicts that the coefficient of age in these regressions will be about the same as the coefficient of age when no sex-role attitude measures are included in the equation (i.e., the coefficient will be about the same as the coefficient of age in equation [1]). The Liberation Hypothesis predicts that the coefficient for age will vanish, or at least be substantially reduced when sex-role attitude measures are included in the equation predicting the coefficient for work plans. Remembering that the coefficient for age in equation (1) is $-.1154$, it is clear from the regression results presented in column A of Table 2 that holding sex-role attitudes constant causes only trivial differences in our estimate of the effect of women's age on the coefficient for work plans in the Basic Model. The coefficient for age is changed only slightly when the effect of sex-role attitudes is held constant. Similarly, looking at column C of Table 2, notice that the correlation be-

tween age and the coefficient for work plans remains high when it is partialled on the various sex-role attitudes. So we have an empirical basis for rejecting the Liberation Hypothesis. We now turn to another hypothesis which competes with our explanation of age differences in the effects of labor force participation plans on fertility expectations.

A second alternative to the Learning Hypothesis is the hypothesis that it is a woman's life cycle stage, not her age, which determines the impact of her labor force participation plans on her fertility expectations. The concept of the life cycle, with regular, sequential stages of development, would seem to have enormous potential as an explanatory variable in the analysis of female labor force participation (Kish and Lansing, 1957; Waite, 1976). Life cycle stages are typically conceived as periods of time bounded by milestones in the life of an ideal-typical individual (Glick, 1947). In research on women's fertility and labor force participation, these milestones would reasonably include the woman's marriage, her first childbirth, and her final childbirth. These events mark obvious time-ordered discontinuities in the experiences to which a woman is exposed. One might conjecture that changes in life cycle stage—rather than a more-or-less continuous process of acquiring knowledge as one grows older, as suggested by the Learning Hypothesis—is the mechanism by which women become more knowledgeable about the demands of child care and, consequently, more likely to curtail their expected fertility to accommodate their plans for employment. And, since life cycle stages are sequential, phenomena which are caused by progress through the life cycle will also be correlated with age. Thus, it is plausible that the relationship that we have observed between age and the coefficient for work plans is spurious and can be accounted for by the correlation between age and life cycle state. We call this plausible alternative to the Learning Hypothesis the Life Cycle Hypothesis.

Since the mean age of women in the NLS sample increases strictly monotonically

⁵ Since we were able to estimate the Basic Model separately for only five age groups, we have only five age-specific coefficients for work plans. Thus, the number of independent variables that can be entered into a regression analysis of these coefficients is extremely limited. So we perform five separate regressions, each one regressing the coefficient for work plans on age and a different sex-role attitude indicator.

Table 2. Regressions of Age-Specific Coefficient for LFPP on Age and Each of Several Sex Role Attitude Indicators^a

Sex Role Attitude Indicator ^b	Metric Coefficient for Age ^c	Metric Coefficient for S.R.A. Indicator	Partial Correlation between Age and Coefficient of LFPP (Net of S.R.A. indicator) ^d	Zero-Order Correlation between Age and S.R.A. Indicator
	A	B	C	D
1. Modern conveniences permit a wife to work without neglecting her family	-.1064	-.3630	-.831	.0766
2. A wife who carries out her full family responsibility doesn't have time for outside employment	-.1033	-.9906	-.943	.0425
3. The employment of wives leads to more juvenile delinquency	-.1101	-.1746	-.843	.0938
4. Working wives lose interest in their homes and families	-.1133	-.3039	-.944	.0262
5. WORKATT (a nine-item Likert scale of attitudes about the costs and benefits of female labor force participation; described in text) ^e	-.1057	-.0891	-.919	-.0181

^a The dependent variable in each of these equations is the metric coefficient for LFPP in the second equation of the Basic Model, the equation for FE. The Basic Model is estimated separately in each of five different age groups, providing an N of five for each of the regressions reported in this table.

^b Items scored on a five-point Likert scale from "strongly agree" to "strongly disagree." The first item listed in this table was scored from one (for "strongly agree") to five (for "strongly disagree"). Items 2, 3, and 4 scored from five (for "strongly agree") to one (for "strongly disagree"). The value of an S.R.A. indicator for an age group is the mean score of the item for women in that age group.

^c Age is the midpoint of the interval which defines each of the five age groups for which the Basic Model was estimated.

^d Partial correlation of Age and coefficient for LFPP net of S.R.A. indicator.

^e WORKATT includes the first four sex-role attitude items listed in this table.

cally with each successive life cycle stage, the coefficient for work plans in the equation for fertility expectations must have a larger value for women in earlier life cycle stages if the Life Cycle Hypothesis is to remain plausible. Looking at columns A and B of Table 3, notice that the coefficients for LFPP are inconsistent with the Life Cycle Hypothesis: the absolute value of the metric coefficient for work plans reaches a maximum at stage 1, decreases from stage 1 to stage 3 and then increases substantially in stage 4. So we have an empirical basis for rejecting the Life Cycle Hypothesis.

It seems worthwhile to stress that we have *not* argued that there are no life cycle stage effects on the impact of work plans on fertility expectations. Rather, we have argued that we have not mistaken those effects (if indeed they exist) for the effects of age. As we mentioned briefly, the effects of life cycle stage on the fertility expectations-work plans relationship is of considerable intrinsic interest, and it would be desirable to investigate those effects in some detail. However, women

have considerable ability to choose when to move from one life cycle stage to another, making it necessary for any research on life cycle stage effects to be designed to avoid biases caused by self-selection into the various life cycle stages. Unfortunately, the most efficient research design for investigating life cycle stage effects is not the most efficient design for investigation of age effects, and we must defer our investigation of life cycle stage effects until some later time.

The Effects of Fertility Expectations on Labor Force Participation Plans, by Age and by Life Cycle Stage

In an earlier analysis, Waite and Stolzenberg (1976) found that NLS women's fertility expectations had only very slight effects on their plans for labor force participation at age 35. We concluded that this finding was surprising, but that it did not contradict earlier research which found that mothers of preschool-age children are less likely to participate in the labor force than women who do not have

Table 3. Effects of Labor Force Participation Plans (LFPP) on Fertility Expectations (FE), by Life Cycle Stage, with Related Statistics ^a

Life Cycle Stage	Partial Regression Coefficient of LFPP in Equation for FE ^b		R ² of Equation for FE	Mean Age	N ^c

2. Married with no children ever born	-0.490 (.292)	-.237 (.141)	.208	23.1	676
3. Married with some children and expecting to bear more children	-0.309 (.394)	-.130 (.166)	.387	24.4	775
4. Married with some children and no more children expected	-0.980 (.394)	-.519 (.209)	.090	26.0	797

^a All variables defined in text.

^b Partial regression coefficients estimated by the method of two-stage least squares. Statistics reported in columns, A, B, and C in this table obtained by estimating the equation for fertility expectations described in Figure 1 separately for women in different life cycle stages. Standard errors of coefficients in parentheses.

^c 447 women were divorced, separated, widowed, not "spouse present," did not report their marital status, or were never-married mothers. These women were excluded from the life cycle stage analyses.

young children (see Sweet, 1968). Rather, we argued that

if childbearing reduces female labor force participation primarily by putting intense pressure on mothers to stay home with their preschool-age children, then finding of negligible effects on fertility expectations on work plans might well be due to the high probability that women in our sample expect that their children will be of school age by the time the respondents themselves are 35 years old. (Waite and Stolzenberg, 1976:249)

If this explanation of our earlier findings is correct, then we should find no large life cycle or age differences in the effects of fertility expectations on work plans. Consistent with this expectation, we find that the effect of fertility expectations on labor force participation plans is uniformly small in all life cycle stages and all age groups in which we estimated the Basic Model. In the five age groups, the metric coefficients are, from youngest to oldest, $-.038$, $-.013$, $-.016$, $-.006$ and $-.050$. Standardized coefficients in those age groups are, respectively, $-.096$, $-.029$, $-.036$, $-.015$, and $-.135$. In the four life cycle stages defined earlier in this paper, the metric coefficients are, from first stage to last, $-.046$, $-.012$, $-.033$ and $.032$. In those four stages, the standardized coefficients are, respectively, $-.123$, $-.025$, $-.079$ and $.060$. (Space limits our presentation of standard errors, R-squared's, etc.; see Suter et al., 1975, for those data.) These findings leave Waite and Stolzenberg's earlier conclusions undisturbed.

Summary and Conclusions

The research reported here was undertaken to describe and explain the effect of young women's age on the relationship between their fertility expectations and plans for future labor force participation. We found that the effect of labor force participation plans on fertility expectations varies from a mild inhibiting effect for 19- and 20-year-olds to a strong negative influence for 27- through 29-year-olds.

To explain this finding, we advanced the Learning Hypothesis. According to the Learning Hypothesis, the inverse ef-

fect of work plans on fertility expectations increases as women age from 19 to 29 because their knowledge of the demands of motherhood and their information about the labor market improve during that time; as women grow older, they become increasingly aware of the extent to which childbearing and childrearing are likely to interrupt their labor force participation and, consequently, reduce the quality of their subsequent employment. As a result, we reasoned that the extent to which women limit their expected fertility to accommodate their employment plans increases as they grow older. The Learning Hypothesis is tested only indirectly in this paper because we lack the data necessary to perform a direct test. However, the hypothesis is consistent with the facts available to us at this time. Further, we test two plausible alternatives to the Learning Hypothesis and are able to reject them both, thereby increasing our confidence in our explanation of age differences in the effect of labor force participation plans on fertility expectations.

If the Learning Hypothesis is true, it would appear to have important implications for certain fertility reduction strategies which have been advanced in recent years. For example, it has been suggested that the birth rate in the United States and other nations can be lowered by increasing employment opportunities for married women (Blake, 1969; 1970; Davis, 1967). The logic behind this proposal is to offer women a choice between careers as mothers and careers as labor force participants. However, our findings suggest that the success of this strategy in reducing *actual* fertility may depend heavily upon the age at which women bear children. If women tend to do their childbearing at an age when the effect of labor force participation plans on fertility expectations is high, then job opportunities which induce females to plan future labor force participation would seem likely to have a large impact on the number of children that women actually bear. But if women tend to do their childbearing at an age when labor force participation plans have only a weak effect on fertility expectations, then economic and social conditions which induce females to plan future em-

ployment seem likely to have only a weak effect on actual fertility, regardless of how much these work plans subsequently might lead mothers to wish that they had been less fertile. However, if the Learning Hypothesis is correct, then the relationship between women's age and the effect of their labor force participation plans on their fertility expectations is not fixed developmentally, but varies as a function of their knowledge of the labor market and the demands of childbearing and childrearing. Thus, it seems possible to use mass educational campaigns to speed up the process by which women acquire this knowledge and, thereby, to lower the age at which labor force participation plans exert a significant impact on fertility expectations. We suspect that an educational campaign of this sort might be used to increase the efficiency of a program designed to reduce population growth by increasing the proportion of women who plan to be employed after childbearing. However, we are acutely aware that we are unable to provide a direct test of the Learning Hypothesis, and so we dare say only that these inferences seem reasonable in light of our findings, but that they must await further, more direct testing before being accepted, let alone applied as part of a population policy.

Finally, a few additional words about our methods and models are in order. Careful readers undoubtedly have remained aware throughout this paper that our measure of fertility expectations, FE, has two components, actual past fertility and expected future fertility. One reasonably might elaborate the models we have utilized here and elsewhere to untangle the three-way relationship between these two fertility expectation components and labor force participation plans. Indeed, consideration of the role of past fertility led us to consider the Life Cycle Hypothesis in this paper, and we suggest that construction of more elaborate models which distinguish past from future fertility would be a logical next step in studying the process by which women's fertility and work plans become interrelated.⁶

However, the present analysis was designed primarily to answer theoretical questions which currently exist in the sociological and, to a lesser extent, the economic and family planning literatures on childbearing and female employment. We have tried to confront those issues in their most basic form as they have appeared in the literature.

Similarly, we believe that another next step would be to include measures of current or past labor force participation in the model. We have left labor force participation experience out of the present analysis because past research implies that the most important effects of work experience are probably not linear and additive but, rather, a series of interaction effects. For example, we would expect that the effects of employment interact strongly with school enrollment status in determining future labor force participation. For those who are enrolled in school, nonparticipation in the labor force probably does not indicate a low propensity for future labor force participation. But for those who are not enrolled in school, nonparticipants are probably less likely to be part of the labor force in the future than women who presently work. Further, according to Mason's (1974) "role hiatus hypothesis," it is not employment or even rewarding employment *per se* that induces women to develop a taste for labor force participation, but it is employment in the absence of marriage that makes career women out of working girls, and so on. The point being made is simply that it is not trivial to add "work experience" to an analysis of fertility and labor force participation plans. Rather than attempt too much in the space of a single paper, we have left considerations of the role of work experience and of the separate effects of past and expected future fertility to later, more complex analyses. We have spent our effort here in understanding some basic features of the effect of age on the link between labor force participation plans and fertility expectations.

⁶ This would be a theoretical as well as an empirical next step, since, to the best of our knowledge,

there is no work whatsoever on the effects of labor force participation plans on parity progressions; but see Hout (1977) for an analysis of other factors related to parity progressions.

ECOLOGICAL APPROACH TO MIGRATION REEXAMINED*

DAVID F. SLY AND JEFF TAYMAN

Florida State University

American Sociological Review 1977, Vol. 42 (October):783-795

The organizational model of migration asserts that demographic responses are the result of organizational change and that they are influenced only indirectly by technological and environmental factors. Previous research has validated the usefulness of this model in developing an understanding of the population migration process in relatively less-developed ecological units. The application of this model to more complex ecological units in this paper, however, calls into question its generalizability and leads to the consideration of an alternative model which postulates that migration is a direct response to environmental conditions and that the influences of technology and organization on migration operate indirectly through their effects on the environment. Support for the environmental model using correlation and path techniques leads to the suggestion that alternative sets of factors influence migration differently at more complex levels of development. Whether organizational or environmental factors influence migration most directly appears to be determined by which is more strongly influenced by technology.

Sly (1972) has developed and tested an ecological model of migration which builds principally upon the works of Hawley (1950), Schnore (1958) and Duncan (1959). According to this model's two major propositions, migration is a response to organizational change, and technology and environment only influence migration to the extent that they elicit organizational change. As Sly

(1972:619) argues, "environment and technology do not operate directly on migration, but effect migration through changes in organization . . . variations in the migration rates of small and large aggregates alike can be explained by observing the effects of variations in external factors on population organization." Despite the viability of this organizational model, Frisbie and Poston (1975) have argued against the temptation to assert causality within complex ecological systems on the grounds that "the direction of causality in ecological systems is surely a function of the point of analytical departure." Thus, although the findings of Frisbie and Poston are supportive of the organizational model, they argue that

* This research has been supported in part by grants from NICHD and the Ford Foundation; Components of Metropolitan Population Change, 1R01-BD09329-02; and Rural Development and Urbanization, 765-0058. We wish to thank Professors Basil Zimmer and Charles Nam for their comments and suggestions as well as the critical eyes of two reviewers.

even though population size may seek an equilibrium with organization, population size must also seek an equilibrium with environmental and technological factors, particularly when the latter are themselves responses to organizational change.

Sly, however, does point out that his test of the organizational model is not wholly adequate; he confines his attention to the migration of black males from 253 Southern cotton belt counties, and suggests that further testing of the model should include consideration of areas with different and more complex sustenance organizations. Thus, although Frisbie and Poston included all nonmetropolitan counties of the coterminous United States in their analysis, they did not include the more urban and more industrialized areas of the United States. They also urge that the type of ecological analysis employed be extended to include consideration of urban areas.

The primary objectives of the present paper are to build upon the works of Sly and Frisbie and Poston by (1) directly testing the organizational model on a group of manufacturing centers and (2) altering the point of analytical departure by posing an alternative model which suggests that migration may be a demographic response to environmental conditions created by organization and technology. If the organizational model can be accepted under the vastly more complex conditions of our sample of areas, its two major theoretical propositions will have gained substantial support; rejection of the alternative model would lend still greater support to the organizational model; while rejection of both models, or the organizational model, would lend support to the notions of the complexity of causality in ecological systems.

The ecological complex as a frame of reference has been discussed in several places (Duncan, 1959; Gibbs and Martin, 1959; Schnore, 1966; Hawley, 1968; Sly, 1972; Frisbie and Poston, 1975) and will not be systematically reviewed here again. Instead, a short discussion will be provided to explain (1) how the sample of areas was selected and (2) why and how the particular indicators employed were selected.

Sample

As noted above, recent research viewing components of population change as demographic responses to changes in sustenance organization has focused upon agricultural and nonmetropolitan areas, and the researchers performing this work have urged others to examine the same questions in more complex areas. Central cities of Standard Metropolitan Statistical Areas seem ideally constituted for this purpose. Their sustenance organizations are complex and continuously undergoing change (Kasarda, 1972; Zimmer, 1975). Similarly, central cities have experienced marked population change, and a considerable amount of their white population change can be attributed to migration (Hawley et al., 1964; U.S. Bureau of the Census, 1971; Morrison, 1974). Yet, cities are vastly different in character and have developed markedly different sustenance organizations (Galle and Williams, 1963; Kasarda, 1972; Yu, 1972). In order to exercise some control over the type of sustenance organization development which has occurred in these areas, we decided to focus upon those with a strong manufacturing base. In part, this decision was predicated on the notion that these areas would have the most developed sustenance organizations (Gibbs and Martin, 1959; 1962; Hawley, 1971) and, in part, on the assumption that a group of manufacturing cities would have experienced vastly different migration experiences (Taeuber, 1972; Berry, 1973).

With these assumptions in mind, we selected central cities of SMSAs having at least 30 percent of their jobs classified as manufacturing (U.S. Bureau of the Census, 1966a). These criteria yielded a sample of 90 cities, 77 located in the industrialized Northeast and North Central states; only one city (San Jose) in the West was included.

Selection of Variables and Operationalization

Ecologically, migration is viewed as a component of areal population change and, as such, it can be considered the other than natural increase or decrease in

areal population size between two points in time. As Sly (1972:615-6) notes, measures of net migration are ideally suited for the type of ecological analysis performed. Estimates of the net migration of the white population for the cities in our sample were obtained from the U.S. Bureau of the Census (1971). These estimates were calculated using the vital statistics method; however, no adjustments were made for boundary changes between 1960 and 1970 and all annexed populations were counted as net migration.¹ Thus, the estimates are biased and tend to overstate net in-migration and understate net out-migration.

This bias, however, does not have any systematic effect upon the data for three reasons. First, one-half of the cities did not annex any new population during the intercensal period and where annexation did occur, it tended to be relatively small—less than ten percent of the 1960 population in another 36 cities. Second, by limiting our attention to the white population, we have reduced further the impact of annexation on the estimates to the extent that each annexed population was nonwhite. Third, the calculated rates of net migration actually used in the analysis further reduced the impact of annexation to the extent that the populations were differentially affected by the out-migration of whites during earlier periods (U.S. Bureau of the Census, 1972). The zero-order correlation coefficient between the percent of population annexed and the net migration rate for the 90 cities was only .032.

To identify relevant independent variables for inclusion in the analysis, we have relied largely upon the work of others (Coe, 1959; Blanco, 1963; 1964; Goldstein and Mayer, 1964; Ullman, 1965;

Greenwood, 1969; Karp and Kelly, 1971; Hansen, 1972; Hawley, 1972; Greenwood, 1973; Winsborough, 1974; Shaw, 1975). The theoretical definitions which guided our classification of these variables as organizational, environmental or technological factors are the same ones employed by Sly (1972) and Frisbie and Poston (1975).

Under the organizational rubric we included (1) the index of industrial dispersion (Sly, 1972) and (2) the percent of the white population which was unemployed in 1960. Under the environmental rubric we have placed three factors: (1) the percent of the central city population which is nonwhite in 1960, (2) the total density of the central city in 1960 and (3) the percent of central city jobs held by noncentral city residents in 1960. In addition to these factors, two technological variables have been included: central city commuting efficiency in 1960 and central city value added by manufacturing in 1960.

The sustenance organization of central cities can be viewed as consisting of four major types of niches: manufacturing, retail, wholesale, and selected services. Since each of the cities in our sample has a manufacturing-oriented sustenance organization and since manufacturing has decentralized in these cities, the index of industrial dispersion measures the access to nonmanufacturing niches (Sly, 1972:620-1). The index was calculated over the four major categories noted above, using data taken from the U.S. Census of Business (U.S. Bureau of the Census 1966a; 1966b; 1966c; 1966d). Although a number of alternative organizational dimensions could have been selected, we decided to focus on industrial dispersion because of its theoretical significance (Gibbs and Browning, 1966) and the fact that a number of studies have already demonstrated its empirical relationship to other organizational dimensions (Rogers, 1957; Clemente and Sturgis, 1972; Kasarda, 1974).

Our second indicator of the sustenance organization of cities taps the dimension of number of niches mentioned by Gibbs and Martin (1959), Sly (1972) and Gibbs and Poston (1975). It is merely the white unemployment rate which gives us an

¹ For convenience of interpreting the migration rates, we multiplied each by a negative one. Since the vast majority of cities lost population as a result of migration, this statistical procedure allows us to refer to those cities having the largest negative net migration rates as having the highest migration. This transformation has been taken into account in the hypotheses presented below. Thus, the hypothesis stating an association between migration and the unemployment rate indicates that as the unemployment rate increases the net out-migration increases.

index of the extent to which the existing sustenance organization is able to absorb the available potential workers in the city. Thus, the index provides a good idea of the extent to which there is an equilibrium between the size of population and the organization of an area (Hawley, 1950:77-9).

The three environmental factors included appear to be straightforward adoptions from previous ecological studies. The percent of the central city population which is nonwhite is an indicator of the competition which whites face for niches, while the percent of central city jobs held by noncentral city residents is another measure of external threat to the white central city population (Blalock, 1956; Heer, 1963). The third environmental variable (density) taps the dimension of "environmental deterioration" of cities, and a number of studies have indicated that high density creates situations from which whites flee (Winsborough, 1974; Humphrey and Krout, 1975).

The two indicators of technology which we employ were picked to be closely related to our indicators of organization and environment. If we assume that the major tool in the organization of sustenance activities is money, then value added to manufacturing is one measure of technological input to the sustenance organization. Moreover, value added is affected by the supply-demand curve for goods produced by the sustenance organization, and in this sense can be viewed as a measure of technological adaptability. The final technological factor considered is the central city commuting efficiency. This index was obtained by taking the total number of in-commuters for each city, subtracting the number of out-commuters, and dividing by the total of all commuters; the measure is synonymous to the measure of migration efficiency (Shryock, 1964; Galle and Williams, 1972). The measure is of particular value because a number of studies have documented relationships between commuting and migration (Goldstein and Mayer, 1964; Termote, 1975). Furthermore, it is a direct measure of not only the extent to which technology allows competition

from outside the central city but also of the extent to which the city population can compete in other environments.

Hypotheses

Applying these data to Sly's model generates seven hypotheses relating each of the independent variables to the rate of net migration:

- (1) The higher the index of industrial dispersion, the lower the net-migration rate.
- (2) The higher the unemployment index, the higher the net-migration rate.
- (3) The higher the commuting efficiency, the higher the net-migration rate.
- (4) The higher the percent value added to manufacturing, the lower the net-migration rate.
- (5) The higher the percent of central city jobs occupied by non-central city residents, the higher the net-migration rate.
- (6) The higher the percent nonwhite, the higher the net-migration rate.
- (7) The higher the density, the higher the net-migration rate.

If the model which views net migration as a direct response to organizational change and only an indirect response to technology and the environment is to gain support, we should find (1) that migration is more closely related to each of the organizational variables than each of the environmental and technological variables and (2) that controlling for the organizational variables will reduce markedly the associations between the environmental and technological factors and migration. The mean and standard deviation for each variable included in the analysis are presented in Table 1.

While the model does imply a number of other hypotheses, like Sly (1972:621-3) we will not deal with these except to note that "if the environmental and technological factors operate as predicted, we would expect them to be more closely associated with the organizational indicators than with migration" (Sly 1972:622).

Table 1. Means and Standard Deviations for the Dependent and Independent Variables, 1960

Variable	Mean	Standard Deviation
IND	.44	.10
WUR	5.01	1.67
CEF	.33	.31
MVA	59.53	22.09

IND =index of industrial dispersion for central cities, 1960

WUR =percent of white labor force unemployed in central cities, 1960

CEF =central city commuting efficiency, 1960

MVA =percent value added by manufacturing in central cities, 1960

CCN =percent nonwhites in central cities, 1960

CJO =percent jobs in central city, held by people living outside central cities

DEN =population per square mile in central cities, 1960

WNM =white net migration of central cities, 1960-1970

Data Analysis

Table 2 shows the zero-order correlation matrix for the variables. Other than the fact that each of the variables operates in the predicted direction with the rate of net migration, there is little support for the organizational model. For instance, each environmental and technological variable is more closely associated with the rate of net migration than are the organizational factors. Similarly, each of the environmental and technological factors should be more closely associated with the organizational factors than with migration; but, in general, this does not seem to be the case. In fact, of the ten comparisons which can be made to determine this, only one (that between value added and the migration rate and value added and the

index of industrial dispersion) shows a closer association between a technological factor and an organizational factor than a technological factor and migration (.403 versus .594).

While these observations tend to mitigate against acceptance of the organizational model, it is possible that when the interrelations between variables are taken into account those relations between environmental and technological factors and migration will reduce substantially below those of the organizational factors and migration. As a first step to testing this, we followed the procedures employed by Sly of examining the association between each of the environmental and each of the technological factors and migration, partialing for each of the organizational factors singularly and then in

Table 2. Zero-Order Correlation Matrix of the Independent and Dependent Variables

combination. Examination of the second-order partials (Table 3) is all that is necessary to indicate that the organizational model has little viability in this context. For instance, although all of the correlations between environmental and technological factors and migration reduce, with the exception of value added, none of the partialled associations are reduced enough to decrease the probability of their acceptance. Again following Sly, we produced a path diagram as a final test of the model. Although not presented, the diagram offers little support for the model since the standardized partial regression coefficients linking the organizational factors to migration were small (-.100 and -.120, respectively), and since the values of all the corresponding coefficients linking environmental factors and migration exceeded those mentioned above by a substantial margin.²

² The path diagram was employed to allow for the simultaneous consideration of all variables and to specify how the variables are seen as operating. The cross-sectional nature of the data employed indicates that the time referent is inferred.

Thus, the data strongly suggest that the organizational model does not work within the context of more industrialized areas and is not nearly as generalizable as previously thought. Duncan (1961), however, has implied an alternative model which stresses the importance of environmental factors in more complex areas although he has not dealt specifically with the issues of demographic responses. In addition to this, a number of other researchers have emphasized environmental factors as being most salient in migration's contribution to population decline in cities (Jacobs, 1961; Butler, 1964; Walpert, 1966; Hawley, 1971; Deutschman, 1972; Morrison, 1974). According to the model implied by these studies, migration is a response to environmental conditions largely created by technological and organizational conditions within the city. This, in turn, implies that technology and organization do not directly affect migration, but that their impact on migration operates indirectly through their effect on the environmental conditions they create as illustrated in

Figure 1. The same seven hypotheses stated above can be used to test this model; however, we will now expect hypotheses one, two, three and four to reduce as controls are introduced.

Partial support for the model can be observed within the correlation matrix (Table 2). First, each of the environmental indicators is more closely associated with migration than are the organizational and technological factors. Second, each of the organizational and each of the technological factors correlate more highly with at least one of the environmental indicators than with migration; however, one of the relationships between an organizational indicator and an environmental indicator (white unemployment rate and central city jobs held by non-city residents) and one of the relationships between a technology indicator (commuting efficiency) and an environmental indicator (density) are not significant. This support for the model justified further analysis so we proceeded following the same strategy employed to test the organizational model.

Table 4 presents the partial correlation coefficients between each of the organizational and each of the technological factors and migration partialing for the environmental factors one at a time and then in combination. By the level of the third-order partials, considerable support for the model is attained. Three of the four possible relationships are not only reduced below the level of significance, but are nearly zero. The only association which does not reduce (and actually increases) is that between the unemploy-

ment rate for whites and migration. Thus, while the model is not totally supported, the data fit this model considerably better than they fit the organizational model and considerably better than Sly's (1972:624) original data fit the organizational model.

Although there is support for the environmental model at the level of the third-order partials, the relations between the first- and second-order partials relative to the third-order partials makes most salient Frisbie and Poston's (1975:782) point about the complexity of cause in ecological systems. For instance, if we examine those partial associations considering the relation between the white unemployment rate and migration, we can see that at the first level of control, two of the environmental indicators (the percent of city jobs held by non-city residents and density) reduce the primary association below the level of significance; yet the control for the percent nonwhite actually strengthens the association. At the second level of control, we can see that when the percent nonwhite is controlled with each of the other two environmental indicators the relationship is strengthened, yet the two operating together reduce the association between the white unemployment rate and migration to nearly zero. This would seem to imply that when all three environmental indicators are considered simultaneously, the association between white migration and the white unemployment rate would reduce substantially. However, this is not the case, and it is clear that the percent nonwhite is a more salient factor than the other two and that the white unemployment rate does have an independent effect on white migration.

Finally, following Sly (1972:626), we consider all of the variables in a path model (Duncan, 1966; Heise, 1969; Land, 1969). This diagram is useful for several purposes.³ First, it lends support to the

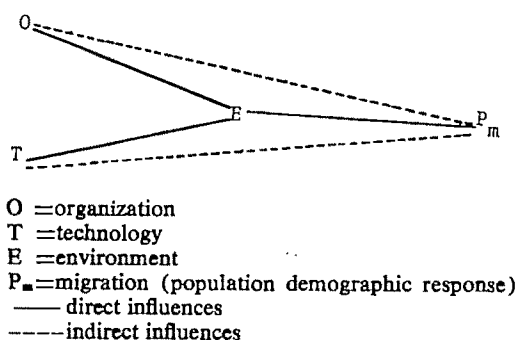

Figure 1. Effect of technology and organization on migration through environment.

³ While the path diagram presented below is suited to our purpose of examining the interrelations between variables, it does introduce the multiple regression consideration of multicollinearity. In this case, the problem does not appear to pose a substantial limitation on the analysis. First, five of the six intercorrelations between exogenous variables are extremely low; second, none of the standardized regression coefficients in the diagram appear to be

environmental model. Nearly 40 percent of the variance in the dependent variable is explained, and each of the path coefficients linking an environmental indicator to migration is stronger than any of the paths linking the organizational and technological indicators to migration. Second, the model clearly illustrates that although all the dimensions of the environment effect migration, the magnitude of their impact varies markedly. The percent of the central city population which is nonwhite, for instance, has about

four times the impact on migration that density does. Similarly, density has less than one-half the impact on migration that the percent of central city jobs held by non-city residents does.

Third, and perhaps most important, is the total pattern of relationships. For instance, although the paths connecting each of the organizational and each of the technological variables to migration are weaker than the paths from the environmental indicators to migration, the paths from the organizational variables to migration are, in several cases, also stronger than the paths from the organizational indicators to the environmental ones. While this could be merely a func-

inconsistent; third, a comparison of the direct and indirect effects of each of the exogenous variables produced no inconsistent results.

tion of the limited number of organizational (and/or environmental) indicators employed (or the particular ones used), it does suggest the possibility that organizational factors do exert a greater independent influence on migration than is suggested in the schematic diagram of the model. Finally, the path diagram also suggests that technological influences on migration operate more through the environment than do organizational influences and that the influences of technological factors on the environment are far more generalized than are the influences of the organizational indicators on the environment. That is, with few exceptions, the values of the path coefficients linking the technology indicators to the environmental indicators are stronger than the corresponding paths from the organizational indicators to the environmental ones.

Discussion

The data presented and analyzed here indicate that population demographic responses, and migration in particular, are not always a direct result of organizational conditions as suggested by the organizational model of migration. The data do indicate that within the context of these modern industrial cities environmental factors are considerably more important than sustenance organization in determining whether a population will increase or decrease as a result of migration. Yet, while the data highlight the importance of environmental conditions in determining the population migration of cities, they also suggest that organizational factors make a contribution to migration which is independent of their indirect effect through the environment. In short, the data highlight the complexity of ecological systems and the importance of the point of analytical departure.

Thus, although it is tempting to reject the organizational model and assert the supremacy of the environmental model, the differences in the nature of the areas studied by Sly (1972) and those analyzed here could indicate the compatibility of the two models and suggest that demographic

responses are elicited more directly by different sets of factors at different levels of areal industrialization. While this proposition cannot be tested with the data at hand, and while the samples are not strictly comparable, it is insightful to draw some comparisons between the path models used by Sly (1972:626) and the one presented here. For instance, he analyzes the migration experience of areas at two different points in time (1940-1950 and 1950-1960) during which their industrial development surely changed. During the earlier period, his environmental indicators had little impact on migration while his organizational indicators did; by the 1950-1960 period, both of the environmental indicators exerted a relatively strong influence on migration. The coefficients from both environmental indicators exceeded those from one of the organizational indicators and the strongest influence on migration was from one of the environmental indicators.

When these observations are coupled with the fact that the organizational indicators we employed influenced migration, but not nearly to the extent that the environmental indicators did, the suggested changing importance of rubrics in determining population change with industrialization seems to gain greater viability.

Similarly, although our areas and populations are not strictly comparable with those studied by Frisbie and Poston (1975), their work demonstrated the importance of organizational factors in determining nonmetropolitan population change. The fact that they explained only about 25 percent of the variance with their organizational factors, however, could suggest that the impact of these were mediated through environmental conditions. Thus, it seems possible that at some point in development population change may become more responsive to environmental than to organizational conditions.

One problem for future research may be to attempt to identify this point and/or to develop further evidence demonstrating the changing importance of the rubrics. Some evidence has been presented to

indicate that the point of the change in the importance of the rubrics may be determined by the influence which technological factors have on the environment, but this inference is based solely on the stronger and more pervasive impact that our technological indicators had on the environmental indicators. For instance, the direct effects of the two technology indicators are negligible (the largest is only .079); yet the total indirect effects of each is substantial with commuting efficiency's indirect effect accounting for about 15 percent of the variance in the migration estimates and value added to manufacturing about 11 percent.⁴ In short, at some point in development, technological factors appear to begin to operate more on the environment than on organization; and when this happens, migration begins to respond more directly to the former than the latter.

Finally, this study, along with those of Sly and Frisbie and Poston, indicates the complex nature of ecological change and the important role which the ecological approach can play in helping to develop a better understanding of population change. Moreover, the analysis presented here helps to demonstrate that the ecological approach is potentially more than a simple heuristic device for ordering and presenting variables. What is suggested, however, is that greater conceptual clarity needs to be developed in order to specify not only the relations between rubrics, but also how factors within rubrics are related. This theoretical development could follow the procedures reviewed by Gibbs and Poston (1975). In this sense, it would be beneficial to specify clearly the structural and processual dimensions of each rubric and then begin to specify (1) the internal operations of rubrics as well as (2) the structures and processes which link rubrics. This type of work would help to explain how and why populations respond

to different sets of factors at different levels of development and it could suggest how and why different demographic responses (migration, fertility, etc.) are elicited.

THE EXPORT OF RAW MATERIALS AND ECONOMIC GROWTH: A CROSS-NATIONAL STUDY*

JACQUES DELACROIX

Indiana University

American Sociological Review 1977, Vol. 42 (October):795-808

World-system and dependency theories suggest that the specialization of some countries in the export of raw materials and lightly processed goods is an important cause of their underdevelopment. The rare empirical evidence in support of this hypothesis is inconclusive because the variables and the designs used are defective. A diachronic multiple regression test using a new version of the theoretical independent variable also fails to provide support for the hypothesis. The test suggests that internal processes play a role that should not be ignored in the economic growth of nation-states.

The study of economic development is a natural meeting ground for social scientists of the several disciplines. Yet, few practitioners of one social science venture far into the preserves of sister disciplines. Sociologists sometimes give cursory attention to economic variables but rarely include them in the models they test. One economic variable of sociological interest is a country's propensity to participate in international exchange markets as a supplier of raw materials. First, this propensity denotes the occupancy of a particular position in a "world-system" (see Wallerstein, 1974a) made up of nation-states. Second, the ability to export goods that are more or less processed depends highly on a country's own internal division of labor and its degree of organization. The latter characteristics, in turn, constitute

an important aspect of the social differentiation of the country or nation-state.

The specialization of countries in the export of raw materials or unprocessed goods has been of interest to theorists of economic development for a long time. For the present purpose, it will suffice to trace back to Lenin the importance attributed to this variable in economic processes. He called the "capture of the most important sources of raw materials" one of the "four principal manifestations of monopoly capitalism" (Lenin, 1917:123 in Selsam et al., 1970:315). Most theorists treat specialization in supplying of raw materials as a position in a world division of labor. The conceptualization nearly always implies a notion of unequal exchange (Prebisch, 1950; Emmanuel, 1972; Baran, 1956; Magdoff, 1969; Frank, 1971; Galting, 1971; Benot, 1973; Amin, 1973; Wallerstein, 1974a). That is, an inherent inequality between the exchange partners is thought to operate more or less consistently to the disadvantage of the raw materials exporters. This perspective suggests the plunder of poor countries by a handful of rich industrialized nations, the exploitation of the many by the few (Lenin, 1917:124). In other words, it pos-

* This paper utilizes data gathered for an unpublished Ph.D. dissertation done at the Stanford University Department of Sociology. The Ph.D. research was financed by National Science Foundation Grant GS 32-65, Mike Hannan and John Meyer, recipients. I am grateful to these two people, to my fellow students in their research project and to Charles Ragin for the error-free advice they gave me. These people do not necessarily agree with the findings presented here.

its surplus value extraction by a macro-class that must set the stage for a new, transnational version of the class struggle. The new version of the class struggle, in turn, heralds the future demise of capitalism in its latest worldwide expression (see, in particular, Wallerstein, 1973; 1974b). This particular version of the relationship between national export specialization and international power relations was already present, though in embryonic form, in Lenin (1917:126) and, possibly, also in Marx (1853:663) and in Selsam et al. (1970:315). It has sociological implications far beyond the more immediate matter of economic growth to which we now turn.

In the past few years, a large number of social scientists and other writers have affirmed or used the idea that specialization in the export of raw materials has adverse consequences for the national economy of the exporter with specific reference to areas of the third world (notably Frank, 1967; O'Connor, 1971; Galeano, 1971, with references to Latin America; N'Krumah, 1967; Berman, 1974 with respect to Africa). Some theorists who are not specifically Marxist have adopted the idea (see, e.g., Heilbroner, 1972:219).

Scholars differ in the degree to which they attribute the specialization of the poor countries in the export of raw materials to the deliberate active intervention of the rich countries. Marxist writers have had a tendency to infer such intervention from a demonstration that it is in the interest of the rich (capitalist) countries to so intervene (Jalee, 1965; Magdoff, 1969; Dean, 1971). Frank (1967) writes of the "development of underdevelopment." Recently, some theorists have focused on the demonstration of a "gatekeeper effect" which involves a rather less conspiratorial view of the rich countries' intervention in the economic affairs of the poor ones. The gatekeeper effect can be summarized as follows. Developed countries maintain underdeveloped countries in their position of raw materials suppliers by controlling the latter's access to the outside world. The developed countries control the underdeveloped countries' access to the capital, the technology and other resources necessary for industri-

alization. This forced inability to industrialize, in turn, perpetuates the relationship by preventing the poor countries from becoming either self-sufficient or exporters of processed goods. The gatekeeper role is assigned variously to the indigenous bourgeoisie (Berman, 1974) directed by foreign capitalist interests and more or less allied to the national military elites (Bourricaud, 1966; Galtung, 1971:85) to transnational corporations acting directly (Petras, 1968; O'Connor, 1970; Seidman, 1970), to international organizations, principally banks (O'Connor, 1970; Payer, 1971) or to a mixture of all of these (Levin, 1966). A few writers have formulated this effect in purely structural terms (i.e., with no implications regarding the gatekeepers' volition—Berman, 1974; Baldwin, 1966). A very small number imply that the managerial incompetence of the government of the countries concerned perpetuates specialization in the export of raw materials or the ensuing adverse economic consequences (Leff, 1968; Tugwell, 1974).

Several processes can be identified as underlying the assumed negative effect of specialization in the export of raw materials on economic health. Empirical evidence in support of the presumed relationship therefore can be brought to bear on the underlying processes or on the relationship itself. In this paper, I summarize the most important underlying processes and review the previous empirical research. I then present and discuss findings of a direct test of the relationship which uses different measures and more up-to-date methods than did the previous research.

Processes

Theoretical explanations of the presumed relationship between specialization in the export of raw materials and national economic welfare pertain to one or a combination of the following processes.

(a) The gradual institution of the European-centered world division of labor in the sixteenth century is elaborately described by Wallerstein. The capitalist world-system rests on more (and more complex) processes than that resulting in

the specialization of areas into exporters of raw and transformed goods. Nevertheless, Wallerstein (1974a:86-126) devotes the better part of one chapter to tracing the intricate linkages between types of commodities produced, systems of labor control, strength of the state apparatus, availability of urban laborers (117-8), the success of indigenous bourgeoisies and the establishment of core capitalism. Wallerstein also describes the varying ability of both peasants and urban workers in the European core areas to share in the ensuing windfall. Hence, *the assignment of what prefigured the present "third world" to the task of providing raw materials (bullion, then food, then materials for industrial transformation) in the sixteenth century is a prime (though not perhaps a primary) cause of the contemporary world inequality*. That this relationship is historically drawn out and causally complex should not obscure its existence, earlier described in more structural terms by Galtung (1971).

(b) *The international demand for raw materials is fundamentally and increasingly inelastic*. The industrialized countries who are the principal buyers of raw material experience very moderate population growth. At the same time, their capacity to perform more and more processing operations on the same quantity of raw material is increasing constantly (Magdoff, 1969). Improvements in the productivity of raw material exporters resulting in increased supply confront a nearly fixed demand. This must result, for the raw material exporters, in lower per-unit prices rather than in growth of income (Furtado, 1965; Gomez, 1966; Maizel, 1968; Galeano, 1971:218).

(c) Logically linked to the last explanation but different in its consequences is the observation that *raw materials prices tend to undergo wide fluctuations*. Such fluctuations tend to make rational economic planning difficult or impossible for the private entrepreneur and the government planner. This state of affairs is aggravated by the fact that the external trade flows of underdeveloped countries implicate a larger portion of their GNPs than is typical for developed countries. This explanation of the unfavorable conse-

quences of raw material export specialization is broadly and critically discussed by Glezakos (1973). (d) Fourth, to the extent that the production of raw materials is financed by nonindigenous interests who repatriate their excessive profits (Gomez, 1966), *the exports of raw materials may result in actual net outflows of cash* (Berman, 1974:6). Finally, Singer (1950), Young (1970), Galtung (1971) and others speculate that *specialization in the export of raw materials results in allocation of national resources that are less than optimal from the standpoint of the exporter's economic growth*. In particular, they allege that such specialization impedes investments in economic and social sectors most likely to have multiplier effects on the exporter's economy.

The net overall thrust of the collection of arguments summarized above is to deny the validity of one of the major tenets of classical macroeconomic theory. According to the Law of Comparative Advantage (Samuelson, 1970:645-67), each actor in the world division of labor must concentrate on what it *does best*, whether or not any other actor does it better. Classical economic theory states categorically that this strategy is in the interest of all the actors.

By contrast, a large and growing body of theory astride several disciplines asserts that a country's specialization in the export of raw materials or unprocessed goods adversely affects its economic well-being. In particular, this body of theory views such specialization as a major obstacle to economic growth and development.

Previous Research

In spite of its high degree of acceptance in the literature, the idea that specialization in raw materials export has adverse effects on economic growth and development is supported by little empirical evidence. What little research on the matter does exist is methodologically unsatisfactory or fails to support the hypothesis.

Some researchers have investigated the link between specialization in raw materials export and economic growth from the viewpoint of price instability. Naya (1973)

finds no statistically significant relationship between the percentage of export in raw materials and the instability of the income of a country derived from exports. His study, using regression analysis, is based on a cross section of seventeen Asian countries presumed to have experienced greater than average export income instability. Glezakos (1973), also using cross-sectional regression analysis, fails to show a significant relationship between the export price instability of forty countries and their growth rates. This result agrees with earlier research by Coppock (1962) and McBean (1966).

Quantitative tests lending support to the hypothesis are scarce. Jalee (1965) and Rollins (1956) construct descriptive tables showing that countries that specialize in the export of raw materials are not rich. Galtung (1971) provides positive support for the hypothesis with cross-sectional bivariate correlations based on sixty countries. His dependent variables are: (a) Gross National Product per capita and (b) percentage of the population employed in nonprimary sectors of the economy. Galtung's measure of export specialization, the Trade Composition Index, expresses as a ratio the balance between the relative degree of processing of the imports and exports of a country. The Trade Composition Index has two defects as a measure of export specialization: (a) as is the case with many compound ratio variables, there are theoretically contradictory ways to get the same score on this measure; (b) Galtung (1971:102) himself signals the second defect: "There is no doubt that this index is a crude measure among other reasons because the variable *degree of processing*, so crucial to the whole analysis, has been dichotomized in 'raw materials' vs. 'processed goods' and because the basis for the dichotomization is the division made use of in U.N. trade statistics." In other words, the dichotomization of products into raw and processed betrays the actual continuity of the theoretical variable *degree of processing*. Any item that reaches a market is the product of human labor on Nature (Galtung, 1971:86) and an investment of human culture into a natural object. Hence, a measure of degree of processing

should admit of an infinity of values except zero. Ideally, each individual item should have its own score denoting this labor and this cultural investment. This is difficult to achieve because of obvious limitations on the availability of data. However, it is possible to minimize the costs of categorizing by using finer categories than Galtung's dichotomy. Finer categories tend to make the observed effect of the measure on other variables less dependent on the exact location of each cutting point between categories.

Galtung expresses reservations about his own use of the U.N. Trade Statistics as a source of data for his index. However, the Standard International Trade Classification used by the U.N. is not fatally inappropriate for this purpose if one makes more use of its features than Galtung does especially if one uses it more critically.

Quite aside from the weakness of the Trade Composition Index, Galtung's test of the hypothesis is inconclusive because of its design. The positive correlation he reports between Trade Composition Index and *percentage of the labor force in non-primary sectors* ($r=.77$) is partly tautological. If, for example, a large percentage of a country's labor force is employed in extractive industries, one would expect that it will be reflected to some degree in the composition of its export which will include some quantities of raw materials. Therefore, percent labor force in non-primary sectors and Trade Composition Index may be, to some extent, two measures of the same internal development variable.

Galtung also reports a high positive correlation between Trade Composition Index and Gross National Product per capita ($r=.89$). Both measures are for 1967-1968. Hence, the test is synchronic rather than diachronic. Such a test leaves open the matter of causation, at least from a narrow, empirical-quantitative viewpoint. Galtung provides rich theoretical argument in support of an interpretation that makes trade composition (or the degree of processing of export) the cause and GNP per capita the consequence. However, it is desirable to test the hy-

pothesis diachronically as well, as he points out (Galtung, 1971:103). Furthermore, since Galtung's test depends on bivariate correlations, the matter of causality cannot be resolved through interpretation of the interrelations of other variables with Trade Composition and with the dependent variables. In particular, it would be useful to test the hypothesis with a design that would include variables chosen to contribute to the elimination of three alternative interpretations of Galtung's findings: (a) National specialization in the export of goods at a low level of processing is a by-product of poverty; it has no direct effect on it. (b) Countries with a large population enjoy a comparative advantage in specializing in the production and export of labor-intensive, low-processed goods. Such countries are primevally poor. (c) While the link between specialization in the export of low-processed goods and poverty is real, such specialization and poverty result from processes *internal* to the country rather than from the operation of the world-system.

I report below on a diachronic test of the hypothesis based on a measure of degree of processing of export that minimizes the difficulties involved with Galtung's Trade Composition Index. In the model tested I include variables designed to facilitate choice between the original hypothesis of dependency and world-system theories and third interpretation above.

Methods

Both substantive and methodological considerations make it advisable to test the hypothesis through a *panel design*. Substantively, it is clear from the literature that the effect of specialization in the export of raw materials on economic variables is viewed as structural and cumulative. Therefore, it must take time; no *instantaneous causation* is considered. The adoption of a panel model is also desirable from a methodological standpoint because it helps solve the problem of *reciprocal causation*. In the real world, things show a tendency to be their own cause. This is particularly true of wealth. It is important

to guard against the possibility that one will attribute to a variable of theoretical interest an effect that is caused by itself over time and that is itself a cause of the theoretical variable. Hence, economic underdevelopment may perpetuate itself *and* force a country into specialization as an exporter of raw material. Such a specialization, in turn, may have *no* independent economic consequences for the underdeveloped country. Cross-sectional designs fail to distinguish between such a situation and one where the specialization causes underdevelopment. With a panel design, by contrast, a measure of the dependent variable at the early point in time can be included in the model. This allows the dependent variable to cause itself over time and apportions the remaining effect among other independent variables included in the model. Therefore, all the equations referred to in this paper are based on a panel design and include a measure of the dependent variable at the early point in time (called the "lagged dependent variable" [see Chase-Dunn, 1975]):

Measures

The literature mentions a variety of ways in which specialization in the export of raw materials impedes economic development. Finsterbusch (1973) has shown that Gross National Product per capita is highly correlated with a multiple indicator measure of the somewhat diffuse concept of development. In the first equation presented, I use *GNP per capita* 1970 as a dependent variable. However, there are well-known difficulties of interpretation associated with ratio variables (Kuh and Meyer, 1955; Briggs, 1962; Schuessler, 1974). Therefore, in a second equation, where (raw) GNP 1970 is the dependent variable, I use a logarithmic transformation of this variable (base 10) because the error variance of this measure may be correlated with other variables in the equation. This second equation also includes a measure of population size in 1955 in order to make the dependent variable in this equation, (raw) GNP, comparable to the dependent variable in the first equation, GNP per capita. It can be shown

that, in a regression with panel design, introducing a measure of population size taken at the *same time* as the dependent variable is nearly equivalent to standardizing the dependent variable by population size. On the other hand, population size measured at the late point in time (1970) of my diachronic model and the same measured at the early point (1955) are highly correlated ($r=.96$). Hence, the inclusion in the model of *population size* measured in 1955 allows one to interpret the dependent variable (raw) Gross National Product as a measure of social welfare, functionally equivalent to GNP per capita. It should be noted that the inclusion of this population measure does *not* in any way make equation (2) an adequate test of the effect of population size on economic growth. I attach no substantive meaning to the estimate associated with this measure because of the extreme complexity of the matter (see Easterlin, 1967).

The data for Gross National Product, 1970 and 1955, come from the International Bank for Reconstruction and Development's 1971 *World Tables* and from its *World Atlas* for 1970.¹ The data for the measure of population size in 1955 were obtained from the Inter-University Consortium for Political Research *World Book of Political and Social Indicators II, Section I* 1971.

Measuring the variable of theoretical interest, degree of processing of export is

¹ *Coding of Gross National Product (GNP)*—Millions of U.S. dollars. This variable was coded from the International Bank for Reconstruction and Development 1971 *World Tables* (Table 4) for 1955. For the year 1970, I used the World Bank's *World Atlas*. There are some minor differences between the two sources' methods for computing countries' GNP. For the years 1950 to 1965, the *World Tables* present the GNP at factor cost expressed in constant 1964 dollars. The *World Atlas* provides figures for 1970 GNP at market prices, using a multi-year period for a base. GNP at market prices includes indirect taxes and is consequently approximately 20% higher, on the average, than GNP at factor cost for the same year. The differences seem, however, to affect all countries about equally. Using a multi-year period for a base for the U.S. dollar reduces temporary distortions. Neither of these differences between the 1970 data and data for previous years is likely to affect findings at the aggregate level. However, one should exercise caution when taking the figures literally for any given country.

a theoretical problem in its own right. Galtung (1971:86) formulates the hypothesis in these terms: the higher the level of processing of the total export of a country, the greater its economic growth. Boulding (1970:20-2), in his discussion of "social species," likens the "direct organization of human ideas and knowledge" which goes into the making of an automobile (an act of processing) to the transmission of genetic information. Likewise, in a previous critique of the labor theory of value, Boulding (1953:164-6) had expressed the idea that raw materials are transformed into products through the injection of social organization in the form of information. Stinchcombe (1968:281-2) remarks that the processing of information generates structural growth. At the same time, he makes it clear that the information content of processed goods (e.g., general cargo) is higher than that of raw materials (e.g., "bulk goods"). Hence, the degree of processing of a marketable product can be expressed in terms of the amount of (social) information invested in it. In this sense, any product is a vehicle for a certain amount of socially organized information.

To measure the degree of processing of a country's export is to assign to the commodities which comprise that export weights that express the amount of social information invested in them. This operation involves two distinct steps. (a) The first is aggregation of commodities. Theoretically, each individual item contains a different amount of information than any other item. The problem here is to make use of the information available to regroup items in a way that comes satisfactorily close to respecting the underlying continuity of the processing dimension (i.e., to improve on Galtung's simple dichotomization). (b) The second step is devising a weighting system expressing the amount of social information invested in the commodities aggregated in step (a) above.

Step (a) of my coding procedure consists in aggregating the breakdowns of countries' exports provided by the *U.N. Yearbook of International Trade Statistics* at the SITC (revised) two-digit "division"

level. The two-digit level is the finest one at which enough countries report the composition of their export. Choosing an even finer level would have caused the loss of cases below the absolute minimum number necessary for regression analysis with significance tests. At the same time, little improvement in precision would have been gained by adopting a finer level of aggregation. The SITC two-digit divisional level classification contains an embryonic scale of degree of processing in crude form. For example, it places: "Textile fibers (*not* manufactured into yarn, thread or fabrics) and their waste" in division 26, while division 65 contains "Textile yarn, fabrics, made up articles and related products." Likewise, the SITC two-digit level distinguishes between division 28: "Metalliferous ores and metal scrap," on the one hand, and division 67: "Iron and Steel" and division 68: "Non-ferrous metals" on the other. However, this classification does not array products according to their degree of processing with enough consistency that we may use it as a *de facto* weighting scheme. Instead, I assign to each division a weight from a scale ranging from 1 (for cattle) to 9 (for transportation equipment). The scale itself is based on a scheme whose basic conceptual unit is the *minimal transformation to which an object must be subjected in order to become a commodity* (i.e., marketable). The scheme takes into consideration comparison between transformations, distance between SITC divisions in terms of number of transformations, additivity of transformations (e.g., transport equipment contains refined metals "transformed" from ore) and the homogeneity of the contents of each division. The measure of degree of processing is computed by multiplying the value of the content of each SITC division expressed as a percentage of total by the weight assigned to that division and summing across. The scores on this measure, called *level of transformation of export*, range, in 1955, from 574 (West Germany) to 128 (Bolivia). Little information seems to have been lost by ignoring imports, since level of transformation of export for 1955 has a rank order correlation of .85

with Galtung's 1967-1968 Trade Composition Index. I use *level of transformation of export*, 1955, as my independent variable of main theoretical interest.²

I use level of transformation of export to try to ascertain the *direct* effect of specialization in the export of raw materials on economic growth for the 1955-1970 period. The problem here is to estimate the influence of a country's position in the world-economy, as denoted by this measure, *over and above* the possible effects of processes internal to the country.

World-system and dependency theories posit that processes internal to each nation-state are consequences of location in the world-system, or they treat such processes as causally secondary. Alternative interpretations of Galtung's findings, (a) and (c) above, depend on the realism of the assumption that internal factors are secondary. Hence, a more complete test of the hypothesis than the one offered by Galtung would incorporate some control for the possible effects of *internal* factors on economic growth.

Following Galtung's general reasoning, the most relevant internal factor here seems to be a country's initial information processing capacity. Galtung argues strongly that raw materials specialization hinders the economic development of poor countries *primarily* by denying them the beneficial "intra-actor effects" that accrue to their industrialized trade partners. In particular, Galtung (1971:87) speculates that raw materials specialization places countries at a relative disadvantage with respect to the expansion of their educational systems. Most of the other intra-actor effects discussed by Galtung can be subsumed under the category of internal differentiation corresponding

² A major conceptual defect of this measure is that it counts only material products. According to the logic of considering processing as an investment of information into objects, the export of pure information—in the form of services—also should be counted. However, it is difficult to combine such exports (for which data are, at any rate, spotty) with commodities. I think that the distribution of scores would not have been much altered by the adjunction of this dimension. I am grateful to the anonymous reviewer who drew my attention to this point with which I fully agree.

to a given capacity for processing information.

Galtung's implicit concept of information processing capacity rejoins the conceptualizations of Duncan (1964:39-41), Boulding (1966), Stinchcombe (1968), Delacroix (1974) and Lenski (1976:556, 558). Lenski and Lenski (1974), for example, make the existing store of generalized information available to a group and the group's changing ability to increase and utilize it the cornerstone of their theory of social change.

Galtung (1971:87) mentions education as one of the concrete manifestations of information processing capacity whose expansion is adversely affected by raw materials specialization. His assumption that educational expansion contributes to the economic development of countries is supported by arguments or findings by Solow (1957), Schultz (1963), Denison (1962), Meyer et al. (1973), Harbinson (1973), Hannan (1974) and, indirectly, by Inkeles and Smith (1974).³ Accordingly, I make *secondary-school enrollment* in 1955 stand for general information processing capacity. I choose secondary-rather than primary-school enrollment because, if this variable has an independent effect on economic growth, it is more likely to be discernible over the time period considered (15 years) than would be the case with primary enrollment. In addition, secondary-school enrollment has lower correlations with population size than does primary enrollment and lower correlation with GNP than does university enrollment. In equation (1) where the dependent variable is GNP per capita, the measure of secondary-school enrollment is expressed as a ratio of the secondary-school-age population. This measure is taken from the 1971 edition of the *UNESCO Yearbook*. In equation (2), which includes a measure of population size and where the dependent variable is (raw) GNP, secondary-school enrollment in 1955 is entered without a control for the appropriate age population. The reason for this omission is that population size

measured in 1955 has a correlation of .99 with the measure of secondary-school age group measured at the same time. Hence, the measure of population size serves the dual purpose of simulating GNP per capita growth (see above) and of controlling for secondary age population.

Finally, it could be argued that equations (1) and (2) constitute an inadequate test of the hypothesis because of the shortness of the lag on which they are based (1955-1970). Wallerstein envisages a process unfolding over several centuries. Galtung seems to hypothesize a slow incrementation of negative intra-actor effects whose aggregate consequence is the purported link between specialization in the export of raw materials and a slow economic growth. Given the existing data limitations, not much can be done to extend the lag between independent and dependent variables measurement. However, it is possible to gain an idea of the *indirect* effect of raw materials specialization on economic growth. There seems to be a consensus around the idea that educational expansion contributes to economic growth. If raw materials specialization has a negative effect on educational expansion, then it must also *indirectly* hinder economic growth though no direct relationship appears for the lag covered. Ideally, one would estimate the effect of the level of transformation of export measured at an earlier point on secondary-school enrollment in 1955. Data limitations make this unfeasible. The next best solution is to make use of what data are available by estimating this relationship for the 1955-1970 period. The results of this operation are presented in equation (3) which is of the same general form as equation (2).

The cases over which the equations presented and mentioned in this paper are computed vary according to the availability of data. Slightly more than half the countries included in each set would have been considered underdeveloped in 1955. All sets exclude the U.S. Close inspection of the residuals associated with each equation shows that while equations (1) and (2) give very similar predictions, equation (2) gives a better prediction for poor countries.

³ While these authors undoubtedly would not agree on the exact nature of the causal path between education and economic growth, they all present evidence in support of the existence of such a link.

Table 1. Pearson Correlations*

	1	2	3	4	5	6	7	8	9
1. Log GNP 1970									
2. Log GNP 1955	.97								
3. GNP/capita 1970	.54	.49							
4. GNP/capita 1955	.47	.47	.94						
5. Level of transformation of export 1955	.70	.65	.61	.49					
6. Secondary enrollment 1970	.71	.65	.82	.74	.68				
7. Second enrollment 1955	.65	.59	.85	.79	.72	.88			
8. Secondary enrollment 1970 as a ratio of secondary age population	.73	.70	.24	.08	.55	.43	.47		
9. Secondary enrollment 1955 as a ratio of secondary age population	.58	.56	.23	.08	.57	.44	.48	.92	
10. Population size 1955	.41	.45	-.12	-.14	.18	.24	-.04	.87	.50

* Pairwise deletion, for all cases for which data were available on level of transformation of export 1955 (N=59, maximum).

Findings and Discussion

The findings directly relevant to the test of the hypothesis are easy to summarize. For the 15-year period covered, initial wealth is the main factor in economic growth as evidenced by the high autoregression terms in equations (1) and (2) ($\beta = .75$ and $.90$, respectively). The estimates of the effect of level of transformation of export on economic growth do not come close to statistical significance in either equation (1) or (2). This lack of significance is not an artifactual consequence of the high autoregression terms in these equations since, in both equations, secondary-school enrollment has a significant positive effect ($\beta = .17$, very close to the $.05$ level in equation [1]; $\beta = .10$, above the $.05$ level in equation [2]).

Equation (3) is a less than perfect test of the plausibility of an indirect linkage between raw materials export specialization and economic growth via information processing capacity. If level of transformation of export affected secondary-school enrollment negatively, it also would indirectly affect economic growth negatively since secondary enrollment has a positive influence on the latter. In equation (3), the beta estimating the effect of level of transformation of export on secondary-school enrollment is negative but very small ($-.01$) and nowhere close to statistical significance.⁴

With all their limitations, these findings do not add up to a confirmation of the widespread belief that national specialization in the role of raw materials supplier to the world-economy is a primary cause of underdevelopment. Rather, these new findings lend some support to interpreta-

⁴ The findings attached to level of transformation of export tend to be very robust. They are not sensitive to small variations in the cases or to time lags over which the equations are computed. Furthermore, controlling for secondary-school-age population in equations (2) and (3), does not change the overall pattern of findings in spite of the multicollinearity this procedure creates. Logging the GNP measures in equation (3) or substituting GNP/capita and secondary enrollment as a ratio of the appropriate age group does not make the coefficients associated with level of transformation of export significant. Finally, logging all the variables to make equations (2) and (3) fully interactive does not alter the conclusions reached.

Table 2. Effects of Degree of Processing of Export on Economic Growth and Secondary-School Enrollment ^a

Equation 1	GNP/Cap 1955	Second Enrollment as a Ratio 1955	Level of Transformation of Export 1955
GNP/Cap 1970	.75	.17	.10
N=49 ^b	(0)	(.06)	(.11)
Rsq=.90	2.05	1070.57	.001
Constant=-.2515			
Equation 2	Log GNP 1955	Secondary Enrollment 1955	Level of Transformation of Export 1955
Log GNP 1970	.90	.10	.06
N=48	(0)	(.04)	(.23)
Rsq=.95	.90	.5 x 10 ⁻⁴	.4 x 10 ⁻³
Constant=1.25			
Equation 3	GNP 1955	Secondary Enrollment 1955	Level of Transformation of Export 1955
Secondary enrollment 1970	.09	.57	-.01
N=47	(.12)	(.00)	(.85)
Rsq=.95	.12 x 10 ⁻⁴	.7 x 10 ⁻⁴	-161.60
Constant=123110.35			

^a In each equation, the first row shows the standardized (beta) coefficients, the second row shows the corresponding significance levels and the third row the unstandardized (b) coefficients.

^b N in equations (2) and (3) includes cases not in equation (1) and vice versa.

tion (c) above of Galtung's previous findings: while there is a positive association between raw materials specialization and initial poverty (evidenced by correlations of .51 and .62, respectively, between GNP/capita 55 and GNP 55, on the one hand, and level of transformation of export in 1955, on the other), the former seems to have little consequence over the short run.

In fact, these findings inadequately express a situation vastly more complex than suggested by the original hypothesis. Strict space limitations prevent me from exploring this adequately but four main points should be kept in mind:

(1) In the short run, wealth leads to wealth. It is difficult to show the effect of anything on national wealth. However, equations (1) and (2) show that *something* does affect national economic growth positively, even in the short run. This something, represented by secondary enrollment, is an internal process rather than an external one as predicted by world-system theory.

(2) The exceptions to the rule that wealth leads to wealth further contradict world-system theory. Equation (2) which gives the best prediction for Turkey, *underpredicts* the economic growth of Libya while it *overpredicts* that of Britain. Libya became *more specialized* in the export of one raw material between 1955 and 1970. Britain's highly processed export in 1955 did not prevent its subsequent relative downfall.

(3) The implicit picture (made explicit by Galtung) of a world neatly divided between poor raw materials exporters and rich processed goods exporters is substantially incorrect. Chile, usually thought of as an underdeveloped country, exports mostly *refined* copper products (70% in 1955) and very little ore (6%). On the other hand, everyone knows that the U.S. and Canada are big exporters of raw agricultural products. Even greater reliance on raw commodities on the part of rich countries is not unexceptional. Iceland tripled its GNP between 1955 and 1970. Yet, in 1955, Iceland's export consisted of very lightly processed or unprocessed fish to the tune of 85%. Argentina, whose agricultural export was only 60% of total

(foodstuff), only doubled its GNP during the same period.

(4) There is no compelling *empirical* reason for ignoring the influence of internal processes on economic development or for treating these processes as mere consequences of world-system position. Chase-Dunn (1975) and Robinson (1976) have recently shown some associations between measures of dependency and national income distribution. Nevertheless, some internal *institutional* factors of economic growth enjoy a degree of freedom from the constraints imposed by initial poverty and by world-system position. Thus, in 1955, the Pearson correlations between secondary enrollment expressed as a ratio of the appropriate population on the one hand and GNP per capita and level of transformation of export on the other were .79 and .71, respectively (N=49). While these associations are not negligible, they indicate that these variables had only about half of their variance in common. This suggests a freedom to maneuver not often acknowledged by exogenetic theories of economic development. Yet, as the OPEC countries have shown recently, some producers of raw materials do maneuver. In particular, they sometimes succeed in obtaining higher payments for their exports of unchanged quality. The conditions under which the terms of trade can be modified through the deliberate actions of exporters are not well studied. Nevertheless, Tugwell (1974) has described the process by which the government of oil-producing countries find themselves in a progressively more favorable bargaining position *vis-à-vis* the foreign corporations operating on their soil. His demonstration puts into question the widespread assumption that the objective interests of indigenous elites in raw materials exporting countries is to act as gatekeepers on behalf of alien capitalist interests (see Galtung, 1971). What *kinds* of national elites will emerge may depend in part on a country's place within the world-economy. The role these elites will play in their countries' economic development may be a joint product of exogenous variables, that more or less facilitate the *management of dependence*, as suggested by Tugwell, and of evolving

internal factors. Among the latter, the information processing capacity of a country, expressed in such things as the overall educational status of its population, must limit the range of available policies.

Finally, the transformation of wealth accruing from exports into industrial development must be influenced by national informational capacity which seems largely independent from the degree of processing of a country's exports.

COMMENTS

REPLY TO PARSONS

In responding to Parsons' (1976) latest commentary on our work, we first treat the two "specific substantive points" he (1976:361) raises and then consider his accusations about our "strict constructionism." We close with additional comments on Parsons' convergence thesis.

SPECIFIC DISAGREEMENTS

Individual Subjective Phenomena in Durkheim's Theory

Contrary to the implication of Parsons' (1976:361) reply, we never argued that (1) Durkheim (1960b:46) said nothing about "*l'ensemble des croyances et des sentiments communs à la moyenne des membres d'une même société*" or that (2) these beliefs and sentiments "have nothing to do with" motivations or subjective intentions of individual actors. Our purpose was to clarify Durkheim's view of the theoretical status in sociological explanation of individual intentions and motivations. There is no doubt that in his definition of the collective conscience, Durkheim (1960a:79, 80) referred to *collective*, not individual, sentiments; the collective conscience is "an entirely different thing from particular consciences." Collective beliefs and sentiments penetrate the individual to become a part of his social personality (Durkheim, 1960a:97, 99). However, even in this internalized state, they remain social, not individual phenomena (Durkheim, 1960a:97, 99, 129-32) and must be analyzed accordingly. In contrast to social phenomena, individual beliefs and sentiments, which vary from one person to another, differentiate and individualize members of a population and constitute an element of individual personality (Durkheim, 1960a:105-6, 129-32).

Durkheim did not view individual subjective states as positable antecedent conditions of social phenomena (Pope et al., 1975:418-9; Pope 1975:374, for full discussion). Moreover, he did not subscribe to the basic tenet of the voluntaristic theory of action that social phenomena are to be dealt with "as they appear from the

point of view of the actor" (Parsons, 1949:46). He was primarily interested not in analyzing action but in explaining *sui generis* phenomena. For example, in *Suicide*, Durkheim (1951:38-9, 46-52, 297-325) emphasized that he wanted (among other things) to explain the social rate of suicide, conceived as an emergent social phenomenon, not the suicidal actions of given individuals. Also, when he discussed "internalization" of collective beliefs and sentiments, he did not link it to a requirement that the phenomena be analyzed from the actor's viewpoint; rather, he (Durkheim, 1960b:35-78) treated the internalization of social phenomena as a process explaining how social phenomena control the unsocialized individual. In sum, far from reflecting a convergence with Weber on the voluntaristic theory of action, the context of Durkheim's references to beliefs and sentiments underscores his distance from both Parsons' voluntaristic theory of action and Weber's (1968:15) view that "subjective understanding is the specific characteristic of sociological knowledge."

Zweckrationalität, Norms and Stability in Weber

Parsons (1976:362) also challenges our interpretation of the place of normative elements in *Zweckrationalität* (instrumentally rational action). First, we did not state that *Zweckrationalität* never involves a normative orientation; rather we (Cohen et al., 1975:235) concluded that "*Zweckrationalität* is not always, or even usually, a normative category of action." Against this, we place Parsons' (1976:362) reaffirmation of his position that *Zweckrationalität* is "one mode of normatively oriented action." If Parsons did not find our earlier analysis convincing, perhaps he would consider Weber's explicit commentary more so. We quote from Weber a passage which deals with economic action and the market (bear in mind Parsons' [1975a:666] statement that Weber "used the conception of economic rationality as the point of reference for formulating" his concept of *Zweckrationalität*):

Many of the especially notable uniformities in the course of social action are not determined by orientation to any sort of norm which is held to be

valid, nor do they rest on custom, but entirely on the fact that the corresponding type of social action is . . . best adapted to the normal interests of the actors as they themselves are aware of them. This is above all true of economic action. . . . The dealers in a market thus treat their own actions as means for obtaining the satisfaction of the ends defined by what they realize to be their own typical economic interests, and similarly treat as conditions the corresponding typical expectations as to the prospective behavior of others. The more strictly rational (*zweckrational*) their action is, the more will they tend to react similarly to the same situation. In this way there arise similarities, uniformities, and continuities in their attitudes and actions which are often far more stable than they would be if action were oriented to a system of norms and duties which were considered binding on the members of a group. . . . The fact [is] that orientation to the situation in terms of the pure self-interest of the individual and of the others to whom he is related can bring about results comparable to those which imposed norms prescribe, very often in vain. . . . (Weber, 1968:30; emphasis added)

In contrast to Parsons' (1976:362) claim that Weber's rational action is normative because it entails the selection of means to ends, Weber specifically denied that selection of means to ends is necessarily normative. Indeed, Weber deliberately *contrasted zweckrational* action with action that is oriented toward norms. Weber's entire passage seems to have been written to preclude precisely the kind of misrepresentation offered by Parsons.

Parsons (1976:362) has asserted that Weber brought in "normative orientation . . . in broaching the problem of how 'social relations' become regularized." However, in the above passage, Weber explained order in terms of the individual's rational pursuit of his self-interest coupled with his expectation that others will do likewise. In contrast, Durkheim (1960a:203-4) in his discussion of "Organic Solidarity and Contractual Solidarity" wrote:

If interest relates men, it is never for more than some few moments. It can create only an external link between them. . . . If we look further into the matter, we shall see that this total harmony of interests conceals a latent or deferred conflict. For where interest is the only ruling force each individual finds himself in a state of war with every other since nothing comes to mollify the egos, and any truce in this eternal antagonism would not be of long duration. There is nothing less constant than interest. Today, it unites me to you; tomorrow, it will make me your enemy.

For Durkheim, the external links created by individual interests at best only temporarily mask an "eternal antagonism." Consequently, he tried to explain social order in terms of the

moral rules which control individual interests. Weber, on the other hand, emphasized that the extent to which normative consensus underlies given social orders varies tremendously; if such consensus underlies some orders, in others such consensus is limited or even absent. While Durkheim considered moral rules the *only* force regulating man's unsocialized desires, Weber emphasized nonnormative bases of order (e.g., usage, custom, habit and self-interest—see Weber, 1968:29, 31, 946-7) as well as normative.

STRICT CONSTRUCTIONISM IN THE INTERPRETATION OF WEBER AND DURKHEIM

Parsons (1976:361) also renewed a charge initially (1975b:106) leveled against "Classic on Classic" (Pope, 1973), rejecting our "strict constructionist" approach as too literal. Parsons (1976:364) implies that our failure to locate convergence is due to our failure to use an interpretive perspective broad enough to capture the essential areas of convergence. However, central to our critique was an analysis *in the very terms posed by Parsons himself*; that is, we assessed the extent to which Weber and Durkheim converged on the voluntaristic theory of action. Ironically, then, his complaint is actually a rejection of his own interpretive perspective.

CONVERGENCE ON THE VOLUNTARISTIC THEORY OF ACTION

In 1937, Parsons argued that Weber and Durkheim converged on the voluntaristic theory of action. Now he (1976:363) asserts that his demonstration of convergence derives from "a conceptual scheme which is somewhat different from (and broader than) those employed by Durkheim and Weber individually, and in some respects broader than can be inferred from their works taken together." Clearly, Parsons' argument has changed: Weber and Durkheim do not converge on a single theoretical perspective; instead, it is only in Parsons' own theoretical framework that Weber and Durkheim come together. This thesis differs from the original; we leave to others the evaluation of the new convergence thesis.

Parsons (1976:364) asserts that in contrast to the situation in 1937, it is now important to "reassess" the differences between Weber and Durkheim and observes that he himself may have "been remiss in failing to point out more explicitly and continuously what some of these are." We regret that Parsons has not taken this

opportunity to identify the most important differences and trace their implications, if any, for his convergence thesis.

"Some thirty-eight years after the publication of *The Structure of Social Action*," Parsons (1976:364) writes, "I 'still' adhere to the thesis of convergence, not in the sense of diminishing confidence, but, on the contrary, of enhanced confidence." He (1976:362) states he "could easily write a large volume of comment" (presumably refutation) about our "assertions and interpretations." However, he offers merely the two examples with which we dealt above, evaluation of which only reinforces our earlier judgments. We can only conclude that the "large volume" would be no more convincing than the two examples.

We have identified essential theoretical divergences between Weber and Durkheim; Parsons has not questioned their fundamental nature. Although it is true, as Parsons (1976:364) states, that one can always find dimensions of similarity and of difference between two theorists, Parsons has yet to demonstrate fundamental similarities between Weber's and Durkheim's theoretical perspectives. Our (Pope et al., 1975:417) original assertion—that the theoretical differences between Weber and Durkheim overwhelm the similarities—stands.

METHODS OF ANALYSIS IN THE STUDY OF THE WORLD-ECONOMY*

(COMMENT ON RUBINSON, ASR,
AUGUST, 1976)

A longstanding critic of modernization theory and the sociology of development, Bernstein (1971:154), has written, "[i]n criticizing modernization theory the intention is not to replace one abstract and rigid schema with another, and the broad generalizations advanced are not to be understood as the necessary and universally applicable elements of an ideal type." In a recent article, Rubinson (1976) purports to test several hypotheses on income inequality generated from the recent literature challenging the conventional modernization approach to development. As a critique of modernization literature, Rubinson's paper is substantively correct, but his analysis contains certain characteristics which tend to rigidify the notion of a world-economy and to leave open possible interpretations which are not at all inconsistent with the modernization and sociology of development approach. The inconsistencies do not arise because of Rubinson's theoretical misconceptions of the nature of the world-economy nor because his intentions are out of line with the critique of modernization theories. The problem is that Rubinson applies conventional methods, mostly suitable to the individual level, static analysis of modernization, to an entirely different problematic. This new problematic, the dynamics of world capitalism, by definition calls for an historical analysis of the unique structural patterns of each country, both developing and de-

* I would like to thank Alejandro Portes and Reynaldo Cue for their comments on this paper. The expressed opinions, of course, are my own.

veloped. The use of aggregate economic data and the lack of detailed class analysis specific to each country lead to inferences about income distribution drawn deductively from a general theory of external control. This type of analysis reifies the conceptual tools of a world-system (e.g., core-periphery), fails to identify the true mechanisms of the internal conditioning of dependent societies and treats the spread of world capitalism in a deterministic manner (Portes, 1976). My comments are intended to point out the problems with Robinson's application of conventional methodologies to the dialectics of the world-economy.

The Use of Static Analysis

Rubinson begins with three hypotheses derived from his excellent theoretical and historical discussion of the mechanisms of control and the relations to the dominant mode of production in the world-system. These hypotheses are: (1) the greater the strength of the state, the more equal the income distribution; (2) the greater the degree of direct foreign control over production, the more unequal the distribution of income; (3) the greater the reliance of a state's production on external resources, the more unequal the distribution of income. Let us examine his analysis beyond its support for these three hypotheses.

Rubinson uses the support for the three above hypotheses to draw conclusions about change within the world-economy. This effort is questionable, as it implies concepts similar to those used in the traditional modernization arguments of development. The world-economy is a dynamic system working under the logic of monopoly capitalism. As a dynamic system, static data and analyses are misleading. Rubinson (1976:649) claims to test the hypothesis that "at early stages of economic development, income inequality is likely to increase but then the effects of development change to reduce inequality." His method is to fit a second-order polynomial to his data, the correct test for a curvilinear trend. The trend is not substantiated. Let us examine more closely the meaning of this test. With cross-sectional data on measures of economic development and inequality, the regression line runs from high inequality and low economic development (dependent nations) to low inequality and high economic development (developed nations). The only way that we can speak of "early stages of economic development" and *changing* income inequality with these data is to assume that the regression line, whether linear or not, represents a functional relationship between these nations on some continuum of

economic development. This continuum implicitly suggests that the underdeveloped nations follow the same course of development as the advanced nations; i.e., they go from one end of the regression line to the other, their distribution of income changing linearly. The assumption that underdeveloped nations will follow a path similar to that of the advanced nations is equivalent to the assumption used in the modernization approach and is actually a central theme of the critique of that literature (Seers, 1969; Bernstein, 1971; Portes, 1974).

Reification of Concepts

In relation to the meaning of the regression line with cross-sectional data, Rubinson, in essence, uses his set of independent variables as means of classifying nations along the developmental continuum from underdeveloped to developed and he shows this classificatory scheme to predict degree of income inequality. As a descriptive effort this is worthwhile and helpful; but as a statement about the development of each nation or about the workings of the modern world-system, the classification scheme is reminiscent of the dichotomies formulated by the modernization literature. Instead of traditional-modern, where degree of structural differentiation and modernity are the bases of classification, we have core-periphery with degree of state strength and equality of income distribution as the classificatory scheme. In both Rubinson's analysis and the modernization literature, definitional categories have become so reified that they are offered as means of explanation. Underdevelopment becomes an act of omission rather than commission. This argument says that nations are underdeveloped not because they are exploited by their relationship to the mode of production in the world-economy or by an international bourgeoisie controlling the strings of economic development but because they lack sufficient state strength, economic expansion, trade balances and protection from foreign investment. Clearly, these omitted characteristics are often evident; however, they are not the cause of underdevelopment nor income inequality but are merely descriptions of the latter's consequences.

Determinism and Lack of Internal Analysis

A third issue relates to the implicit notion of a developmental continuum in Rubinson's method of analysis. While the peripheralization of the third world resulted from similar processes of the spread of capitalism, these processes did not occur in the same fashion

COMMENTS

REPLY TO PARSONS

In responding to Parsons' (1976) latest commentary on our work, we first treat the two "specific substantive points" he (1976:361) raises and then consider his accusations about our "strict constructionism." We close with additional comments on Parsons' convergence thesis.

SPECIFIC DISAGREEMENTS

Individual Subjective Phenomena in Durkheim's Theory

Contrary to the implication of Parsons' (1976:361) reply, we never argued that (1) Durkheim (1960b:46) said nothing about "*l'ensemble des croyances et des sentiments communs à la moyenne des membres d'une même société*" or that (2) these beliefs and sentiments "have nothing to do with" motivations or subjective intentions of individual actors. Our purpose was to clarify Durkheim's view of the theoretical status in sociological explanation of individual intentions and motivations. There is no doubt that in his definition of the collective conscience, Durkheim (1960a:79, 80) referred to *collective*, not individual, sentiments; the collective conscience is "an entirely different thing from particular consciences." Collective beliefs and sentiments penetrate the individual to become a part of his social personality (Durkheim, 1960a:97, 99). However, even in this internalized-state, they remain social, not individual phenomena (Durkheim, 1960a:97, 99, 129-32) and must be analyzed accordingly. In contrast to social phenomena, individual beliefs and sentiments, which vary from one person to another, differentiate and individualize members of a population and constitute an element of individual personality (Durkheim, 1960a:105-6, 129-32).

Durkheim did not view individual subjective states as positable antecedent conditions of social phenomena (Pope et al., 1975:418-9; Pope 1975:374, for full discussion). Moreover, he did not subscribe to the basic tenet of the voluntaristic theory of action that social phenomena are to be dealt with "*as they appear from the*

point of view of the actor" (Parsons, 1949:46). He was primarily interested not in analyzing action but in explaining *sui generis* phenomena. For example, in *Suicide*, Durkheim (1951:38-9, 46-52, 297-325) emphasized that he wanted (among other things) to explain the social rate of suicide, conceived as an emergent social phenomenon, not the suicidal actions of given individuals. Also, when he discussed "internalization" of collective beliefs and sentiments, he did not link it to a requirement that the phenomena be analyzed from the actor's viewpoint; rather, he (Durkheim, 1960b:35-78) treated the internalization of social phenomena as a process explaining how social phenomena control the unsocialized individual. In sum, far from reflecting a convergence with Weber on the voluntaristic theory of action, the context of Durkheim's references to beliefs and sentiments underscores his distance from both Parsons' voluntaristic theory of action and Weber's (1968:15) view that "subjective understanding is the specific characteristic of sociological knowledge."

Zweckrationalität, Norms and Stability in Weber

Parsons (1976:362) also challenges our interpretation of the place of normative elements in *Zweckrationalität* (instrumentally rational action). First, we did not state that *Zweckrationalität* never involves a normative orientation; rather we (Cohen et al., 1975:235) concluded that "*Zweckrationalität* is not always, or even usually, a normative category of action." Against this, we place Parsons' (1976:362) reaffirmation of his position that *Zweckrationalität* is "one mode of normatively oriented action." If Parsons did not find our earlier analysis convincing, perhaps he would consider Weber's explicit commentary more so. We quote from Weber a passage which deals with economic action and the market (bear in mind Parsons' [1975a:666] statement that Weber "used the conception of economic rationality as the point of reference for formulating" his concept of *Zweckrationalität*):

Many of the especially notable uniformities in the course of social action are not determined by orientation to any sort of norm which is held to be

valid, nor do they rest on custom, but entirely on the fact that the corresponding type of social action is . . . best adapted to the normal interests of the actors as they themselves are aware of them. This is above all true of economic action. . . . The dealers in a market thus treat their own actions as means for obtaining the satisfaction of the ends defined by what they realize to be their own typical economic interests, and similarly treat as conditions the corresponding typical expectations as to the prospective behavior of others. The more strictly rational (*zweckrational*) their action is, the more will they tend to react similarly to the same situation. In this way there arise similarities, uniformities, and continuities in their attitudes and actions which are often far more stable than they would be if action were oriented to a system of norms and duties which were considered binding on the members of a group. . . . The fact [is] that orientation to the situation in terms of the pure self-interest of the individual and of the others to whom he is related can bring about results comparable to those which imposed norms prescribe, very often in vain. . . . (Weber, 1968:30; emphasis added)

In contrast to Parsons' (1976:362) claim that Weber's rational action is normative because it entails the selection of means to ends, Weber specifically denied that selection of means to ends is necessarily normative. Indeed, Weber deliberately contrasted *zweckrational* action with action that is oriented toward norms. Weber's entire passage seems to have been written to preclude precisely the kind of misrepresentation offered by Parsons.

Parsons (1976:362) has asserted that Weber brought in "normative orientation . . . in broaching the problem of how 'social relations' become regularized." However, in the above passage, Weber explained order in terms of the individual's rational pursuit of his self-interest coupled with his expectation that others will do likewise. In contrast, Durkheim (1960a:203-4) in his discussion of "Organic Solidarity and Contractual Solidarity" wrote:

If interest relates men, it is never for more than some few moments. It can create only an external link between them. . . . If we look further into the matter, we shall see that this total harmony of interests conceals a latent or deferred conflict. For where interest is the only ruling force each individual finds himself in a state of war with every other since nothing comes to mollify the egos, and any truce in this eternal antagonism would not be of long duration. There is nothing less constant than interest. Today, it unites me to you; tomorrow, it will make me your enemy.

For Durkheim, the external links created by individual interests at best only temporarily mask an "eternal antagonism." Consequently, he tried to explain social order in terms of the

moral rules which control individual interests. Weber, on the other hand, emphasized that the extent to which normative consensus underlies given social orders varies tremendously; if such consensus underlies some orders, in others such consensus is limited or even absent. While Durkheim considered moral rules the *only* force regulating man's unsocialized desires, Weber emphasized nonnormative bases of order (e.g., usage, custom, habit and self-interest—see Weber, 1968:29, 31, 946-7) as well as normative.

STRICT CONSTRUCTIONISM IN THE INTERPRETATION OF WEBER AND DURKHEIM

Parsons (1976:361) also renewed a charge initially (1975b:106) leveled against "Classic on Classic" (Pope, 1973), rejecting our "strict constructionist" approach as too literal. Parsons (1976:364) implies that our failure to locate convergence is due to our failure to use an interpretive perspective broad enough to capture the essential areas of convergence. However, central to our critique was an analysis *in the very terms posed by Parsons himself*; that is, we assessed the extent to which Weber and Durkheim converged on the voluntaristic theory of action. Ironically, then, his complaint is actually a rejection of his own interpretive perspective.

CONVERGENCE ON THE VOLUNTARISTIC THEORY OF ACTION

In 1937, Parsons argued that Weber and Durkheim converged on the voluntaristic theory of action. Now he (1976:363) asserts that his demonstration of convergence derives from "a conceptual scheme which is somewhat different from (and broader than) those employed by Durkheim and Weber individually, and in some respects broader than can be inferred from their works taken together." Clearly, Parsons' argument has changed: Weber and Durkheim do not converge on a single theoretical perspective; instead, it is only in Parsons' own theoretical framework that Weber and Durkheim come together. This thesis differs from the original; we leave to others the evaluation of the new convergence thesis.

Parsons (1976:364) asserts that in contrast to the situation in 1937, it is now important to "reassess" the differences between Weber and Durkheim and observes that he himself may have "been remiss in failing to point out more explicitly and continuously what some of these are." We regret that Parsons has not taken this

opportunity to identify the most important differences and trace their implications, if any, for his convergence thesis.

"Some thirty-eight years after the publication of *The Structure of Social Action*," Parsons (1976:364) writes, "I 'still' adhere to the thesis of convergence, not in the sense of diminishing confidence, but, on the contrary, of enhanced confidence." He (1976:362) states he "could easily write a large volume of comment" (presumably refutation) about our "assertions and interpretations." However, he offers merely the two examples with which we dealt above, evaluation of which only reinforces our earlier judgments. We can only conclude that the "large volume" would be no more convincing than the two examples.

We have identified essential theoretical divergences between Weber and Durkheim; Parsons has not questioned their fundamental nature. Although it is true, as Parsons (1976:364) states, that one can always find dimensions of similarity and of difference between two theorists, Parsons has yet to demonstrate fundamental similarities between Weber's and Durkheim's theoretical perspectives. Our (Pope et al., 1975:417) original assertion—that the theoretical differences between Weber and Durkheim overwhelm the similarities—stands.

METHODS OF ANALYSIS IN THE STUDY OF THE WORLD-ECONOMY*

(COMMENT ON RUBINSON, ASR, AUGUST, 1976)

A longstanding critic of modernization theory and the sociology of development, Bernstein (1971:154), has written, "[i]n criticizing modernization theory the intention is not to replace one abstract and rigid schema with another, and the broad generalizations advanced are not to be understood as the necessary and universally applicable elements of an ideal type." In a recent article, Robinson (1976) purports to test several hypotheses on income inequality generated from the recent literature challenging the conventional modernization approach to development. As a critique of modernization literature, Robinson's paper is substantively correct, but his analysis contains certain characteristics which tend to rigidify the notion of a world-economy and to leave open possible interpretations which are not at all inconsistent with the modernization and sociology of development approach. The inconsistencies do not arise because of Robinson's theoretical misconceptions of the nature of the world-economy nor because his intentions are out of line with the critique of modernization theories. The problem is that Robinson applies conventional methods, mostly suitable to the individual level, static analysis of modernization, to an entirely different problematic. This new problematic, the dynamics of world capitalism, by definition calls for an historical analysis of the unique structural patterns of each country, both developing and de-

* I would like to thank Alejandro Portes and Reynaldo Cue for their comments on this paper. The expressed opinions, of course, are my own.

veloped. The use of aggregate economic data and the lack of detailed class analysis specific to each country lead to inferences about income distribution drawn deductively from a general theory of external control. This type of analysis reifies the conceptual tools of a world-system (e.g., core-periphery), fails to identify the true mechanisms of the internal conditioning of dependent societies and treats the spread of world capitalism in a deterministic manner (Portes, 1976). My comments are intended to point out the problems with Robinson's application of conventional methodologies to the dialectics of the world-economy.

The Use of Static Analysis

Rubinson begins with three hypotheses derived from his excellent theoretical and historical discussion of the mechanisms of control and the relations to the dominant mode of production in the world-system. These hypotheses are: (1) the greater the strength of the state, the more equal the income distribution; (2) the greater the degree of direct foreign control over production, the more unequal the distribution of income; (3) the greater the reliance of a state's production on external resources, the more unequal the distribution of income. Let us examine his analysis beyond its support for these three hypotheses.

Rubinson uses the support for the three above hypotheses to draw conclusions about change within the world-economy. This effort is questionable, as it implies concepts similar to those used in the traditional modernization arguments of development. The world-economy is a dynamic system working under the logic of monopoly capitalism. As a dynamic system, static data and analyses are misleading. Rubinson (1976:649) claims to test the hypothesis that "at early stages of economic development, income inequality is likely to increase but then the effects of development change to reduce inequality." His method is to fit a second-order polynomial to his data, the correct test for a curvilinear trend. The trend is not substantiated. Let us examine more closely the meaning of this test. With cross-sectional data on measures of economic development and inequality, the regression line runs from high inequality and low economic development (dependent nations) to low inequality and high economic development (developed nations). The only way that we can speak of "early stages of economic development" and *changing* income inequality with these data is to assume that the regression line, whether linear or not, represents a functional relationship between these nations on some continuum of

economic development. This continuum implicitly suggests that the underdeveloped nations follow the same course of development as the advanced nations; i.e., they go from one end of the regression line to the other, their distribution of income changing linearly. The assumption that underdeveloped nations will follow a path similar to that of the advanced nations is equivalent to the assumption used in the modernization approach and is actually a central theme of the critique of that literature (Seers, 1969; Bernstein, 1971; Portes, 1974).

Reification of Concepts

In relation to the meaning of the regression line with cross-sectional data, Rubinson, in essence, uses his set of independent variables as means of classifying nations along the developmental continuum from underdeveloped to developed and he shows this classificatory scheme to predict degree of income inequality. As a descriptive effort this is worthwhile and helpful; but as a statement about the development of each nation or about the workings of the modern world-system, the classification scheme is reminiscent of the dichotomies formulated by the modernization literature. Instead of traditional-modern, where degree of structural differentiation and modernity are the bases of classification, we have core-periphery with degree of state strength and equality of income distribution as the classificatory scheme. In both Rubinson's analysis and the modernization literature, definitional categories have become so reified that they are offered as means of explanation. Underdevelopment becomes an act of omission rather than commission. This argument says that nations are underdeveloped not because they are exploited by their relationship to the mode of production in the world-economy or by an international bourgeoisie controlling the strings of economic development but because they lack sufficient state strength, economic expansion, trade balances and protection from foreign investment. Clearly, these omitted characteristics are often evident; however, they are not the cause of underdevelopment nor income inequality but are merely descriptions of the latter's consequences.

Determinism and Lack of Internal Analysis

A third issue relates to the implicit notion of a developmental continuum in Rubinson's method of analysis. While the peripheralization of the third world resulted from similar processes of the spread of capitalism, these processes did not occur in the same fashion

throughout the periphery. That is, the periphery is not a homogeneous mass related to the core through standardized mechanisms of control. Instead, capitalism has penetrated each country within the context of its own unique history. Class formations, patterns of state control and the influence of foreign investment are not only the consequences of this penetration but are the results of the *synthesis* of historical internal social relations interacting and conflicting with the forces of foreign economic and political control. It is, in fact, the nature of the world-economy that the search for wage levels where sufficient surplus can be extracted leads to a wide range of economic, political and social relations. This heterogeneity cannot be justly served by an analysis which lumps widely different countries together in an averaging type of analytical procedure. Regressing characteristics of those countries named in Appendix 3 (p. 657) says little about how the penetration of capitalism has affected income inequality or, indeed, what relationship each country bears to world production. This averaging technique leads to broad generalizations which offer little explanatory power or practical application. For example, Robinson (p. 644) writes, "Since the state is relatively weak [in the periphery], workers cannot effectively use access to the state to apply political leverage to meet demands for higher wages." However, leaving aside the fact that Robinson's treatment of state power offers few insights into actual power relationships, one is immediately reminded of the situation in Chile under Allendé and contemporary problems in Argentina where a highly organized labor force continually pressured the state for wage increases, to the point of causing a drastic state reaction. In short, the absence of any analysis specific to each country fails to identify those mechanisms of control which prevent development and encourage income inequality (Petras, 1975).

Methodology and Theory

General questions should be raised about the appropriate methodologies to be used in studying emerging paradigms of development such as the world-system. The ahistorical, cross-sectional regression analysis represented in the Robinson paper can lead to erroneous theoretical interpretations of change for reasons noted above. This type of analysis is a major contributor to the "economistic" thinking (Amin, 1974) of many developmentalists; i.e., the underdeveloped nations are just a little late in starting the race for advancement so let us help by giving them just a little more of what they

lack. We can see that the regression coefficient in this cross-sectional analysis is easily translated into this kind of policy thinking; a one-unit increase in state control of resources will move a country farther up the income equality continuum and, therefore, the developmental continuum. As Robinson (p. 652) writes, "these measures of the strength of states in relation to other states do have independent, though small, effects in reducing the degree of income inequality." However, changing position in the world-economy does not result from incremental change but from transformation of a nation's social and economic structure, a concept Robinson recognizes in his discussion but does not represent in his method of analysis. One method for studying this transformation is to examine inductively the historical patterns of countries which have changed their position in the world-economy. The ready examples are those nations which have recently moved to a position in the "semi-periphery" (Wallerstein, 1974), a concept Robinson ignores totally, lumping these nations into his developmental continuum. Only with nation-specific and true comparative studies of structural transformations can the mechanisms of control which produce income inequality within the world-system be identified.

Longitudinal analyses (e.g., Chase-Dunn, 1975) offer a more appropriate test of hypotheses relating to the world-economy. But, while techniques of analyzing longitudinal data will identify trends and covarying relations in time, we are still left with the likelihood of making economic inferences from these trends (Cardoso, 1973). The problem is that these techniques often lead to interpretations which "de-dialecticize" structural change. The dynamism of the world-economy is derived from its dialectic form. A central question which needs to be debated is how can the sophisticated statistics required to sort out many of the complex relations in a world-system be applied creatively and effectively to a dialectical system? Certainly, we cannot criticize sophisticated statistical technology on the grounds that it is too complex, but we can criticize it according to how it is managed. The analysis in Robinson's paper is one case where the benefits derived from the power of statistical technology may be outweighed by the costs to the theoretical framework, i.e., the crucial issues of structural transformation and change, which is the root of the world capitalist system.

Finally, let me comment on the use of "proxy variables" in this analysis. Clearly, all measurement is only a representation of reality and the task is to push continually to minimize

the latitude of this approximation. The question, however, is not simple. In efforts to measure social reality, we are placing a certain conceptual framework on that reality. The conceptualization of social reality in a dialectic system like world capitalism implies a holistic approach. The use of aggregate economic measures to represent external control, power relations and class formations tends to compartmentalize this holism. Therefore, when a measure of the proportion of state revenues to total GNP is offered as a proxy for state power, one must be extremely cautious in attributing much explanatory power to it. The issue is not only how much this revenue amounts to but to whom does it go and why?

In conclusion, these comments have only hinted at many of the complex issues underlying ongoing attempts to study the structure of the world-system and unequal relationships within it. These issues will arise continually as more studies of specific hypotheses are undertaken. Researchers must be careful that their methods truly address the theoretical notions of a world-system and do not compartmentalize, rigidify and reify the concepts derived from them. My sole purpose in these comments has been to identify and to call for debate on those problems of using existing methodologies, largely designed for the analysis of comparative statics, to study alternative paradigms of national development and underdevelopment.

CROSS-SECTIONALISM: MISMATCHING THEORY AND MODEL

(COMMENT ON RUBINSON,
ASR AUGUST, 1976)

According to Rubinson, economic wealth or growth can explain only inadequately inter-country differences in equality of income distribution. His introduction of international context effects seems promising, but the cross-sectional model used provides more answers to the wrong questions. The analysis also contains several statistical and operational problems, but primary attention must be given to the assumptions underlying the cross-sectional model used since at present it is probably the dominant comparative paradigm.

Rubinson's (1976:640, fn. 1) theoretical argument proposes an "effect" of the "position of states in the world-economy" on within-state income distribution. More specifically,

the basic idea is that the greater the economic dominance and influence that states . . . have in the world-economy, the more equal the distribution of power within states, and consequently, the more equal the distribution of reward.

As stated, the idea seems sound. But in passing from idea to model, Rubinson adds, I think, a theoretically unjustified provision about equality seen cross-sectionally. Clearly, an increase in relative power may well improve a nation's internal equity without affecting its equality of income distribution relative to other nations.

Theoretical arguments discussed by Rubinson focus, among other things, on the "mechanisms affecting income distribution . . . class formation . . . production and occupational structure . . . [and] class relations" (pp. 643-4). Each of these involves changes in parameters within countries: "This paper compares

the distribution of income within states and studies the way in which the position of states in the world-economy affects this income distribution" (fn. 1). Thus, we should expect a comparison of this within-country relationship *among* countries. Interestingly, Robinson's analysis of historical evidence does exactly that, though limited by the data problems he notes (pp. 644–5).

What is not expected is the subsequent empirical examination of that relationship with cross-sectional analysis of cases. In other words, Robinson's theoretical reasoning specifies a relationship between variables that is appropriate *within* cases; the theory does not directly concern cross-sectional comparison of variables. As Lieberman and Hansen (1974) and Kuznets (1963) (both cited by Robinson) demonstrate, the cross-sectional relationship between two variables can be quite different from their relationship within cases. It was a surprise to see these particular articles cited since it is in these works, among others, that one finds explicit challenge to the validity of the cross-sectional paradigm used. (See also Kuznets, 1962; Riley, 1973; Schaie and Labouvie-Vief, 1974.)

In the second part of that same historical analysis, Robinson finds a system-specific factor that influences the relationship between economic growth and income distribution but he does not seem to notice it. He offers evidence that in certain (highly developed) countries, the distribution is more or less stable over time while in other (less developed) countries, high degrees of inequality accompany high growth rates. He does not attempt the identification of a general factor (level of development?) affecting the relationship. Yet, the "primary function of comparative inquiry" is the identification of such general factors (Przeworski and Teune, 1970: 13). Suggesting that the world-economic model may be more appropriate than a developmental model at this point (p. 646) seems premature in light of the untested possibility of such a "context effect, whereby the context operates in an interactive manner" (Przeworski and Teune, 1970: 69). Assuming an otherwise correctly specified model, such an effect would mean that the within-country relationship changes systematically with increases in the independent variable. Regressing within-country slopes on mean power measures for each country could show a systematically changing sensitivity of income distribution to further changes in power.

It is not all together fair to ask for such an intensive analysis with the type of "soft" data available, but then neither is it fair (or logical)

to call on single-point, cross-national data, no matter how "hard," to make causal inferences—unless it can be shown or assumed that the relationship between the variables is equivalent for all cases (Somers, 1971: 384). This means that Robinson has had to assume all countries develop along the same schedule; that if country A comes to occupy country B's position of power, it also will have the *same* income distribution, regardless of A's former distribution. Robinson's theory does not predict this developmental equivalence. To assume such equivalence mismatches theory and model, not an unusual event in cross-national comparisons.

To further clarify this mismatch, consider a relationship between two variables that is strongly positive and linear, *within all cases*. This condition does *not* require the slopes or intercepts to be equal, but only $b_{yx} > 0$ for each country. Seldom are theories more explicit in any case and Robinson's is no exception. To require the same slope within each case, allowing for different historical backgrounds (or intercepts), would orient the regression lines all in the same parallel direction. To further require the relationship be equivalent across cases would require all regression lines to merge into one.

We now select single points on each regression line requiring only that each $b_{yx} > 0$. Even when the theoretically predicted within-country relationship holds, these cross-sectional data coordinates need not show a relationship. If there is a cross-sectional relationship, it need not have the same slope or even the same sign (see Przeworski and Teune, 1970: ch. 3, esp. 64–8). Thus, if both within- and across-country slopes are the same, a rather special condition obtains: the same condition of equivalence required for a cross-sectional test to be appropriate for causal hypotheses. This condition is not part of Robinson's theory, and the context effect mentioned above suggests the condition does not hold.

The hypotheses described (p. 647), in short, were not tested. We do not know what the effect of increasing political power (etc.) is on inequality of income distribution within a country, because no data on covariation of these variables within a country are offered. Even if we want to assume that the functional relationship is the same for all countries operating *in vacuo*, the fact is that they are not. Nation-states occasionally learn from their own and others' history; the experience is diffused in countless ways. Controlling for date of independence (p. 648) is an unsatisfactory and generally irrelevant answer to this challenge. An analysis of covariance, as in Schuessler (1971:

238-46), would have been a more appropriate model for the hypotheses (if not the data) considered in this article.

Turning to the theory itself, we see that "power and control in the world-economy" (p. 641) is a function of (1) internal political control, (2) economic penetration abroad and (3) independence from the external market. We may accept for the moment that a "strong state structure" will enhance a nation's relative position in the world-economy for the reasons given (p. 642), but "direct economic penetration" abroad is difficult to achieve while simultaneously maintaining independence from "external markets." Generally, it does not seem consistent with the benefits derivable from exploiting international comparative advantage to propose that a nation will increase its "dominance and influence" in the world-economy by becoming independent from it. Absolute independence implies no contact. Without international trade, we also may wonder how strong the structure of a modern state can be. One questions whether there can be such a thing as independence *and* prosperity in today's industrial world-economy (Cooper, 1968).

It is at best a peculiar conceptualization of power within a "system," the components of which are isolated, yet Robinson's operationalization of "weakness" seems to advocate such a conceptualization: "Just the fact of having to import or export puts the state . . . in a position of less power and control in the world-economy" (p. 654). Given the perennial concern among industrialized countries over balance of payments, it seems more plausible that it is not *lack* of activity but more activity of one kind (exporting) than of another (importing) that implies power. The same sort of questions come up in Robinson's (pp. 651-2) separate regressions of foreign reserves and external public debt; each alone may only indicate scale rather than quality of activity. It would seem that some sort of *net* measure would be more appropriate to the operational needs here unless we insist that *any* economic activity abroad weakens a state.

Admittedly, Robinson qualifies his argument about economic penetration and external control by distinguishing between "raw products" and manufactured items (e.g., p. 642). To test whether the amount of a certain product exported (or imported) affects inequality, he includes the value of the particular product in the regression. However, the preceding argument he cites by Galtung (p. 655) concerns not *amount* of value but *specialization*, particularly in food and raw materials: the amount of a product-type exported (or imported) may

merely reflect scale and efficiency or surplus (as in the U.S.). A more appropriate operationalization for his purposes might be one where such exports are calculated as a proportion of all exports or of GDP.

Robinson's empirical results and his interpretation of them are at once instructive (e.g., his commendable concern with "overall patterns") and perplexing (e.g., his inconsistent approach to statistical inference). The key to interpreting the several tables is in the regression coefficients: if a given independent variable affects inequality as predicted, then we should see (1) a negative effect on the Gini coefficient (for "overall" inequality) and (2) a *negative* effect on the share of income controlled by the wealthiest sector (or Q_5) and a *positive* effect on the lowest (Q_1) (p. 647). The latter indicates the direction of change of relative distribution of income from the richest to the poorest sectors.

For the first independent variable (economic development), Robinson claims the model is supported. But the model predicts *positive* effects on the bottom quintile(s) and negative effects on the top. In fact, both are affected negatively: the share of income accruing to the middle groups is increased by (significantly) reducing both the richest *and* poorest groups' shares (p. 649). Nor is this an isolated instance of Robinson's finding support for an hypothesis when that is not clearly indicated in the data.

Also, we see that the standardized regression coefficient for government revenue on overall inequality (Gini) goes from -0.289 ($p < .05$) in Table 2, to -0.406 ($p < .05$) in Table 6 when debits and capital formation are controlled, even when n decreases from 47 to 39, respectively. In light of conclusions drawn from much less in the article, a change of this magnitude and significance deserves some explanation. One might conclude, for instance, that the effect of government revenue on inequality does *not* remain the same, demonstrating that the various mechanisms of power and control in the world-economy have *interdependent* effects on the degree of material inequality. In fact, Robinson concludes the opposite (p. 653).

Several disturbing practices harm the article's statistical credibility. The text compares regression coefficients that do not reach significance (even at .10) with those that are significant (at .05) and therefore can be generalized (e.g., pp. 650, 652). Such comparisons seem to put significance in a (sometimes appropriate) secondary place. But the comparison (p. 650) of the relative independent effects of government revenues and economic

COMMENTS

development on inequality apparently depends on a standard multiple regression decomposition of statistically significant contribution to explained variance. Such uses of significance seem inconsistent.

Less serious but still disturbing are such lapses as, in Table 5, the coefficients for foreign reserves: "In all cases the slopes are greater than their standard errors" (p. 652). Having thus attracted our attention to it, we notice the coefficient for Q_4 . Other hypotheses were found "supported" even when some of the relevant standard errors were greater than the regression coefficients. (All together, $SE_b > b$ for about 15% of the coefficients reported, or at least one such coefficient in nearly 80% of the regression equations.) Moreover, how does one interpret the eight pairs of (standardized and unstandardized) coefficients that are of opposite signs? (e.g., Table 3, the coefficients for government revenues on the Gini index).

Rubinson's article illustrates that cross-sectional comparisons may be both misleading and missing the point of comparative social inquiry. The crucial unit of comparison is not the case, whether nation, economy or individual, but the functional relationship operating within and among the units of analysis or cases. Theoretical reasoning ordinarily specifies relationships that are operating within each case (Blalock, 1972: 426) as, for example, that between power and inequality within nations. Further, rather than assume that the relationship between power and inequality is equivalent from one nation to another, changes in that relationship should be the focus for comparison. In Rubinson's case, we may attribute the use of the cross-sectional model to lack of longitudinal data (Lieberson and Hansen, 1974: 524); however, the frequency of cross-sectionalism in comparing nations, even when time-series data archives are relatively readily available, suggests other basically logical reasons for its current dominance. Repeated (mis)use of the model in empirical research, in spite of its known limitations, may have led to its unconscious acceptance logically and theoretically. (See Nisbet's [1976: 97-8] criticism of Parsons [1966].)

REPLY TO BACH AND IRWIN *

One of the major concerns of the social sciences has been to describe and explain the origins and development of the modern world. During the past twenty years, work on this problem has been dominated by the theoretical approach known as modernization or development theory. In this conceptualization, the countries in the world exist at different stages of modernization or development, and the

* I would like to thank Chris Chase-Dunn, John Ralph and Dan Quinlan for their comments on this paper.

AMERICAN SOCIOLOGICAL REVIEW

basic problem is to specify the conditions under which countries proceed from a stage of underdevelopment to a stage of development. More recently, this same problem has been reconceptualized by what is known as the world-system perspective. In this conceptualization, the countries in the world are seen as located within a single economic division of labor. And, as in any division of labor, groups that perform different roles produce different class structures and different political forms. The basic problem is to study this system's process of production and exchange, the creation and utilization of power, and the organization and maintenance of inequality. Countries are not independent entities in this system, but they represent political structures within different economic roles in the single division of labor (Wallerstein, 1974).

In the paper critiqued by Bach and Irwin, what I did was to approach a problem dealt with extensively by modernization theorists, the explanation of inter-country differences in income inequality, from the world-system perspective. I argued that much of the difference in inequality could be explained as a consequence of the position of countries within the world-system. From this perspective, I argued that the basic mechanisms affecting income distribution were class formation, the production and occupational structure, and class relations. I argued that these factors were not exogenous variables, but were themselves a function of the position of countries within the world-system, such that the creation of certain forms of class formations in some countries created certain complementary forms in other countries. From this theoretical analysis, I generated some testable hypotheses, tested them by cross-national regression analysis, and found that the hypotheses were confirmed. I concluded by arguing that the world-system approach seemed more valid than the modernization one.

Neither Bach nor Irwin directly question the theoretical analysis. Rather, they are both concerned with the methodological approach used in the empirical analysis, and they raise the issue of the relationship between the theory and the method. Bach argues that the world-system framework is a "new problematic" which "by definition calls for an historical analysis of the unique structural patterns of each country." Irwin argues that no theory about countries is testable through cross-national comparison, and that only an analysis of covariance design is appropriate for comparative research.

Their basic concern seems to be that statisti-

cal methods, in this case cross-national regression analysis, implicitly assume specific substantive theories. Neither Bach nor Irwin are raising the more usual issue that any statistical method is based on certain statistical assumptions, for example, about the nature of the error process or the shape of relationships among variables. Rather, they are raising issues about the *philosophy* of method. They are arguing that for each substantive theoretical approach, there is a specific type of method required. The question they raise is fundamental, but I disagree with their answers.

Bach and Irwin raise three specific issues: (1) that a regression analysis assumes a developmental or modernization theory, (2) that countries are unique and therefore analysis must be on a case-by-case basis and (3) that longitudinal analysis is preferable to cross-sectional analysis.

Regression analysis and development theory. Both Bach and Irwin assert that using a regression technique assumes that nations must develop along a set path; and since the world-system approach argues that nations do not, then regression is an inappropriate method for testing this theory. But all a regression analysis does is to describe the relationship between variables, in this case by minimizing the sum of the squares of the errors. The variables that are included in the model and the interpretation of the process relating the variables are derived from the substantive theory of the researcher. They are not contained within the statistical method of minimization. Just because a line can be drawn along which countries can be ordered does not imply that all countries must develop along a set path. That a regression analysis does not assume a developmental theory should be obvious from the fact that such analyses are used in all kinds of fields to test many different kinds of theories.

Irwin misunderstands Robert Somers' discussion of the assumption of developmental equivalence. (Somers' choice of this term is unfortunate here, since he is not discussing the substantive theory of development.) Somers is simply pointing out that in the use of a cross-section regression model for causal analysis, the researcher is assuming that *if* a unit were to change its values on the independent variables in the model, then it would change its value on the dependent variable in the manner described by the regression coefficients. This assertion is, of course, true; for it represents exactly that hypothetical experimental manipulation which lies behind *all* nonexperimental research. This same assumption applies to both cross-sectional and longitudinal designs and to all

forms of nonexperimental causal analysis. The point which Irwin misses is the hypothetical *if*. Somers is not saying that the unit *has* to change its values on the independent variables; rather, he is saying *if* it does change on those values, *then* it would change its value of the dependent variable. I think it is this misunderstanding of the nature of nonexperimental research which allows Irwin to argue that because I employed regression, I "had to assume all countries develop along the same schedule."

The claim that regression analysis implies developmental or modernization theory seems quite widespread to me (cf. Moul, 1974). I suspect this idea arose because modernization theorists often have used regression analysis to test their hypotheses, while other types of theorists of development have not; but this is certainly no reason to think that regression implies a specific theory of development. This claim is just incorrect.

Uniqueness and historical analysis. Both Bach and Irwin also raise the issue of the uniqueness of countries. Bach argues that any analysis must be on a case-by-case basis and comparing across countries is invalid. Every country is unique; but that is not to say that relationships among variables are unique. This issue had been discussed at length by Zelditch (1971), so I will not pursue it here at any length. Simply put, if one's interest is in knowing everything about a country, then one should research the history of that country. But if one's interest is in theory, then one should study relationships among variables; and the fact of uniqueness is irrelevant toward that purpose.

However, I do not think that Bach really wants to do history but rather, the theory of underdevelopment. He understands that the process of peripheralization has been basically the same (in many respects, not all) across countries since the emergence of the capitalist world-system in the sixteenth century. I think what Bach objects to is the fact that modernization theory does not fit the historical data for countries, and that such theorists almost totally have neglected to see whether their theories fit such data. But that is no reason to imply that there is a specific "historical methodology." Historical data, if we want to use that term, is merely older than contemporary data; but that does not give it any different logical status. I think that we presently have only one empirical methodology. Historical and contemporary analyses all have the same logical status, and all must confront the same problems. In terms of the logic of empirical inquiry, I see no difference between the empirical logic in the analyses of Wallerstein or Bar-

rington Moore and the research designs to which Bach objects. The important issue is how well one does the research, not the logical status of different kinds of research.

Irwin, too, emphasizes the uniqueness of countries, but in a very different way. He makes two claims. First, he asserts that any theory about relationships among variables in countries cannot be tested by comparing across countries, but only within countries. Second, he asserts that comparative research consists *only* in the identification of system-specific factors which alter the relationship among variables across countries. From these two assertions, he argues that my theory could not be tested by my research design. His first assertion is incorrect, and the second one confuses theory and method.

Irwin says that since my theory asserts that state strength reduces inequality within countries, then that hypothesis cannot logically be tested by comparing the relationship between these two variables across countries. Does he also think that a hypothesis relating social class to educational aspiration among individuals cannot be tested by comparing individuals? He says that my hypothesis logically can only be tested longitudinally within countries. Here Irwin is misunderstanding the basic idea of a unit of analysis. A unit of analysis, as he correctly notes, is simply an instance of the replication of a process (Zelditch, 1971: 282). Therefore, to test the relationship between state strength and inequality, one can use any instance in which these two variables occur, providing the scope conditions of the theory are met. A set of valid units for comparison, then, may be found in time (a time-series analysis), in space (a cross-sectional analysis) or in both time and space (a panel analysis). Any theory can be tested in any or all of these ways, because what is being compared is the relationship among variables. There is no one proper or improper unit of analysis. As Zelditch (1971:282) states, "one cannot assume that units are somehow out there in the real world, independent of our conceptualization of them." From the point of view of the logic of research, testing my hypotheses by comparing the relationships across countries is equally as valid as testing them by comparing the relationships across time periods.

Consider Irwin's claim that my hypothesis relating state strength to inequality cannot be tested by comparing across countries but only over time within a country. If we use this latter design and assume that the proper lag for this relationship is ten years, then the unit of analysis is, for example, Chile from 1935 to

1944, from 1945 to 1954, from 1955 to 1964, etc. The test of the hypothesis consists in comparing the relationship between state strength and inequality across time periods. This comparison is a valid test of the hypothesis; but it is no more or less valid than comparing the relationship between the variables across countries. In the first case, the comparison is over time; in the other case, the variation is over space. From the logic of empirical research, both comparisons are equally valid, since both types of comparisons are comparing instances of the replication of the process.

For Irwin to claim that only comparison within a country over time is a valid comparison, he needs to have a *theory* which asserts that only variation over time, as opposed to space, meets the conditions for the process to operate. Irwin does not have such a theory, nor does the theory I developed make such a claim. Irwin is taking what must be a theoretical assertion and turning it into a methodological fiat. If one were to make a theoretical claim that variation over time within a country met the conditions for the process to operate, whereas variation across countries did not, then one is making quite strong claims about the uniqueness or particularness of countries. But why should this be true? Is Chile from 1935 to 1944 really the same as Chile from 1965 to 1974? In many ways, Chile is obviously not the same, for the form of regime differs, the occupational structure differs, and many other features differ. Similarly, countries differ in their form of regimes and their occupational structures; but none of those differences are what matters for the logic of comparison. The only thing that matters is that what is being compared, time periods or countries, is a replicate of the process.

Irwin claims to find empirical evidence for his assertion that the relationship between state strength and inequality varies radically across countries. He points out that "the standardized regression coefficient for government revenue on overall inequality (Gini) goes from -0.289 ($p < .05$) in Table 2, to -0.406 ($p < .05$) in Table 6. . . ." But if one wants to compare causal effects across equations, then one must compare the unstandardized coefficients (Blalock, 1967). In Table 2, that coefficient is -0.006 ; and in Table 6, that coefficient is -0.007 . That difference is not significant.

Finally, let us consider Irwin's claim, taken from Przeworski and Teune (1970), that comparative research consists only in the identification of system factors which alter the relationships among variables across countries. This is the basis for Irwin's claim that only an

analysis of covariance design is appropriate for cross-national research. From my previous argument, it should be clear that there is no *a priori* methodological basis for such a claim. Such a statement is a theoretical assertion. But Przeworski and Teune are taking a theoretical claim and, like Irwin, converting it into a universal methodological directive. This is a confusion between theory and method. One could have a theory about how relationships among certain variables differ under certain conditions. In this case, one appropriate test of such an hypothesis would be to use an analysis of covariance design. I have, in fact, done such an analysis elsewhere (Rubinson, 1977); but this is just a case of matching a specific hypothesis to a specific research design. There is no reason to claim that this is either the goal of comparative research or the only appropriate research design for such research. I believe, however, that Przeworski and Teune make this assertion because they implicitly believe that countries really are unique, and therefore comparisons across countries are not useful. They, like Irwin, present no theoretical reasons for such an assertion. Rather, they make methodological claims about an issue which is theoretical.

Cross-sectional versus longitudinal designs. A third point which both Bach and Irwin make is that longitudinal designs are better than cross-sectional designs. I also agree with this assertion; and if I had had sufficient longitudinal data, I would have employed a longitudinal design. However, recognition of the superiority of longitudinal over cross-sectional designs does not provide an *a priori* basis for an assertion that the results of cross-sectional designs are not correct. This is an empirical question which must be decided instance-by-instance. The conditions under which inferences derived from cross-sectional and longitudinal analyses converge have been discussed elsewhere, and there is no need to repeat them here. I want to make just one comment on this issue, for I think it is misunderstood by many researchers.

Many researchers seem to feel that the use of a longitudinal research design, in which the independent variables are measured in time before the dependent variable, is sufficient to prove the hypothesized causal ordering of the model. This is not correct. There are an innumerable number of misspecifications which will "fit" any set of longitudinal data, just as there are an innumerable number which will "fit" any set of cross-sectional data. A longitudinal design is no panacea for research. A longitudinal design is only *one* step better than a cross-sectional design. More important than one's research design is one's theory, for no

model is better than the theory from which it is derived.

Miscellaneous issues. Both Bach and Irwin raise a number of smaller and diverse issues. I will answer a few of them in the remainder of this comment.

Irwin wonders what the conclusions from certain of my analyses would have been if I had changed the order of entrance of the independent variables in the equations. He is assuming, here, that I used some type of stepwise procedure for estimation. I did not. All independent variables in all equations were entered simultaneously, which is consistent with the theoretical model. He is correct when he points out that one coefficient I said was larger than its standard-error in Table 5 was not. But this correction does not change the substantive conclusions that I drew from the analysis. Irwin also wonders how to interpret those pairs of standardized and unstandardized coefficients which are of opposite signs. They should be interpreted for what they are—printing mistakes. The verbal exposition in the paper clearly specified the sign of those effects. Finally, both Bach and Irwin confuse hypotheses that I derived from modernization theory with those I derived from the world-system perspective. Thus, Bach says that I slip into the perspective of modernization theory when I test the hypothesis that “at early stages of economic development, income inequality is likely to increase but then the effects of development change to reduce inequality” (Rubinson, 1976: 649). Here I am explicitly testing the modernization hypothesis, not my own. Similarly, Irwin thinks that in my discussion of Table 1, I am incorrectly finding support for my own hypothesis, when I am actually showing that the modernization hypothesis that level of development reduces overall inequality is not supported in the analysis (Rubinson, 1976: 649).

Conclusion. In conclusion, it is important to go back to the original and fundamental objections to my analysis. Both Bach and Irwin argued that the method by which I tested my hypotheses was invalid because of the kind of theory I was using to approach the question of inter-country differences in inequality. Their objections, I pointed out, raised questions about the philosophy of methodological inquiry. They both assert that the usual forms of empirical inquiry are invalid. I have tried to explain why I believe they are incorrect. If we were to adopt their prescription and require a different method for different theories, then we would never be able to test the validity of different theories, because there would be no way to untangle empirical results from

methodological technique. The real problems in research are not methodological but conceptual and theoretical.

SOCIAL CONSTRUCTIONS AND URBAN ETHNICITY

(COMMENT ON YANCEY, ERICKSEN AND JULIANI: ASR JUNE, 1976)

In their article, Yancey et al. (1976) attack the assimilationist and pluralist perspectives in American sociological studies of ethnicity. The major contention of the article was that the concentration of “pluralists” and “assimilationists” on the explanatory power of cultural origins as determinates of ethnicity in urban America is ill-founded. It was suggested by the authors that the role of a constellation of urban, historical, ecological, industrial and growth factors was of greater moment than that of an imported culture in the formation, maintenance and development of American urban ethnic identities. Although I accept the main thrust of the authors’ criticisms and also agree that the variables discussed are important

ones, Yancey et al. seem at least partially guilty of not practicing what they preach.

Their claim that "the development and persistence of ethnicity is dependent upon structural conditions characterizing American cities and position of groups in American social structure" (p. 391) is incomplete. One may clearly benefit from an analysis of these factors in trying to understand variations in the salience of ethnicity for any particular group in numerous situations. But the implication of the article is that the definition of the ethnic unit itself is not problematical, nor is mention made of the possible effect of these very factors on variations in ethnic definition. Yet one of the most important sociological questions concerning the generation of urban ethnic identities revolves around the use, acceptance or rejection of particular ethnic labels in various contexts and the effect which various, even discrepant definitions of ethnic entities have on ethnic response and the generation of new identities.

To give a very brief example, New Zealand recently has been experiencing an influx of migrants from the Cook Islands, Tokelaus, Fiji, Tonga, Western Samoa and Niue as well as the urbanization of its Maori population. As they get caught up in the urban milieu, specific factors discussed by Yancey et al. affect ethnic response. Yet these people, as different from each other as Poles, Jews, Italians, Greeks, Irish and Germans, may be labeled "Polynesian" in certain situations and treated as an undifferentiated ethnic group. Although this is a source of some resentment on their part, Pacific Islanders and Maoris are forced to accommodate to or confront these *pakeha* (white) definitions of the situation. In the course of doing so, their identities undergo some interesting changes. Literature dealing with American cities briefly discusses similar situations (e.g., Glazer and Moynihan, 1963; Hannerz, 1974) as do articles concerned with other areas.¹ Although I will not review these or the complex ethnic kaleidoscope I researched in Papua New Guinea towns (Levine, 1976), the point to stress is that ethnic identities as emergent phenomena arise through social interaction. They are constructed, objectified, etc., by interacting individuals whose social constructions fundamentally affect the course which ethnic emergence takes. Various factors may condition that interaction but they

do not determine the form of any particular "ethnic culture."

Without this perspective, the authors' argument remains culturally deterministic in regard to the form which particular identities take. Using their ideas alone, one still must rely on "cultural" definitions of urban ethnic units,² taking them as they are found and assuming their present form existed "since time out of mind" (Horowitz, 1975:113). The authors do briefly indicate that they are aware that new ethnic identities form in urban America (e.g., the hillbilly community mentioned on p. 397); but although we may all agree that the city is the place to look for the generation of such local identities, the constellation of specific factors discussed in the article is inadequate for a complete understanding of ethnic formation processes. Intensive studies of ethnic formation must take social interaction, the negotiation of identities, etc., centrally into account. Although an interactionist perspective used alone would be incomplete, a combination of the authors' ideas with empirical studies of the meaning, use, implications, etc., of various ethnic labels would be most productive. In this way, one can avoid some of the pitfalls in which ethnic studies have often become trapped.

NEO-ETHNICITY AS DEFENSIVE POLITICAL PROTEST

(COMMENT ON YANCEY, ERICKSEN AND JULIANI, ASR JUNE, 1976)

There is an obvious problem with our understanding of ethnicity. We had thought the salience of ethnicity was generally diminishing, when within the last decade there appeared a resurgence of ethnic solidarity and identification. This raises two questions. What is to be made of this neo-ethnicity, and does this invalidate the assimilation thesis? Present thinking seems to be that this ethnic revival reflects a persistence of ethnicity as an important factor in American life, and that the melting pot thesis may have been premature (Glazer and Moynihan, 1970; 1975; Novak, 1971; Greeley, 1971).

Yancey et al. (1976) also adopt the anti-assimilation position, but with an interesting twist. They argue that ethnicity should not be considered a fixed cultural quotient that either simply persists, as in the pluralist version of America, or gradually diminishes, as with the assimilation thesis. Ethnicity, in effect, ebbs and flows, depending upon the ecological structure of the cities in which ethnic groups find themselves. If people are commonly grouped by occupation and residence and share common institutions and services, then ethnic solidarity should flourish and persist; if these factors are absent, ethnicity should diminish.

I want to argue with Yancey et al. on three interrelated points. (1) We cannot speak of ethnicity as if it were one unified phenomenon. The highly *politicized* ethnic solidarity of the past decade is quite different from the notion of ethnicity as customs, religious practices, language, neighborhood networks, and everything else one ordinarily means by "ethnic." Yancey et al. conceive ethnicity in this way, but the most distinctive aspect of the new ethnicity is that it is largely a matter of *defensive political protest*. An evaluation of whether ethnicity is persisting or diminishing must take into ac-

count its recent political character. (2) Political protest and defensive solidarity movements are not generated by the simple ecological structure of cities. The intervention of the national government in local politics and the growing political power of blacks are generating white ethnic protest as they resist the threats to their dominance of city politics. The causes of this ethnic solidarity are political, not ecological. (3) Taking the political character of ethnicity into account leads one to conclude that this outburst of ethnic solidarity should be seen as one of the last gasps of resistance to assimilation, rather than as an indicator of ethnic persistence. Ethnic solidarity reflects neither the persistence thesis, nor the ebb and flow thesis of Yancey et al., but reinforces the original assimilation proposition.

Ethnicity as Defensive Political Protest

Whether we say "blue collar" or "lower middle-class" or "homeowner" in New York City, or whether we say "Italian" or "Irish" is not unimportant, and yet we know we are talking about roughly the same people. So the mass media discourse about the "white ethnic groups" or the "white working- and lower middle-class"—the people are the same, and the issues are the same: their feelings that they have been ignored, have received little from government in recent years, and have borne the brunt of the costs involved in the economic and political rise of the Negroes. (Glazer and Moynihan, 1970:xxvi)

Since about the time of Wallace's 1964 primary campaigns and the emergence of the "white backlash," we have experienced an almost unending succession of demonstrations, protests, complaints and collective violence by white ethnics against the intrusion of the national government into local politics to improve the status of blacks.

There have been protest marches, demonstrations and violence in resistance to court-ordered busing, as in South Boston; conflicts between white teacher associations and black administrators, as in the Ocean Hill-Brownsville fight over decentralization (Ravitch, 1974); struggles over who will control the police, as seen in the resistance to Police Review Boards (Abbott et al., 1969) and increased militancy by police officer associations (Bop, 1971); bitter mayoralty elections between white ethnic and black candidates (Levy and Kramer, 1972); a new militancy among voluntary associations which were traditionally of the self-help variety; and support for national politicians like Wallace and Agnew who opposed the extension of federal power into local politics and reaffirmed the sanctity of

family, neighborhood, church and authority in general (Lipset and Rabb, 1970).

The origins of this protest and conflict are not the simple ecology of the city. The Irish of South Boston do not express ethnic solidarity simply because they share common occupations, residential stability, or common institutions (the variables of Yancey et al.), but because they are reacting to an attack upon the local privilege of controlling schools. Their ethnic pride is a *defensive reaction* to an external threat. Similarly, many of the local heroes of the new ethnicity, such as Louise Day Hicks of Boston, Frank Rizzo of Philadelphia, Anthony Imperiale of Newark or Albert Shanker of the AFT, have gained their fame from engaging in defensive political activity and defending the slipping position of ethnic groups in the structure of local politics.

Nation-Building and Local Resistance

Defensive solidarity movements are a regular aspect of the political process, occurring throughout the history of nation-building in the West. The reaction of American cities during the past decade can be seen as another instance of the resistance of local polities to the expansion of state power. Local protest movements, in the form of food riots (Tilly, 1971), anti-tax and anti-conscription riots (Tilly et al., 1975), and the protest of the so-called Parisian "little people" (Rudé, 1959) to the intrusions of the new regime during the French Revolution, seem to occur at periods when the national government is expanding its authority at the expense of local sovereignty. Rudé's (1959:225) observations on the protest of the Parisian "little people" is applicable to the ethnic protest of today. They protested "not to renovate society or to remodel it after a new pattern, but to *reclaim traditional rights and to uphold standards* which they believed to be imperilled by the innovations of ministers, capitalists, speculators, agricultural 'improvers,' or city authorities" [emphasis mine]. The ethnic protest over schools, police, city hall, and shifting moral standards is a similar defensive protest to *reclaim traditional rights* which are being *imperilled* by the intrusions of the government and growth of black political power.

Since the early 1960s there have been unprecedented federal challenges to the local structure of power and authority. The object here was not the building of a national economy, levying taxes, or conscripting an army, as in the earlier expansion of state authority, but extending the rights of national citizenship to blacks. Between the Great Society programs

of the early 1960s, with their community action projects and threats to withhold federal funds, the civil rights legislation of the mid-1960s, the court-ordered busing for school integration in the late 1960s and the affirmative action policies of the 1970s (Glazer, 1976), city governments have been under almost constant pressure to share political power with blacks. These local polities, like their European brethren earlier, react with protest. Ethnicity is so merged with the substance and structure of city politics that federal intervention into local politics becomes not only a crisis in local authority but also a crisis in ethnicity itself.

The Institutionalization of Ethnicity in the Organization of City Politics

Along with the usual idea of ethnicity as a cultural heritage, it has persisted in an *organizational* form, in the reality of city politics. The ousting of native Yankee-Protestant control from large northeastern cities was one of the principal means for immigrant mobility (Hofstadter, 1955). "Public employment was a major channel for the Italian, the Irish, and the Jew, each of whom by successively taking over whole sectors of the public services, gave various municipal agencies their distinctive ethnic coloration. Now blacks are the newcomers" (Cloward and Piven, 1975:227). The political machine and patronage system provided a means for perpetuating ethnic control over cities, a control that only now is being challenged by the new "immigrants," the blacks. In America, city politics have been ethnic politics (Banfield and Wilson, 1963) in that they are both the institutionalization of group advantage (controlling city hall, schools, etc.) and a symbol of the presence and persistence of ethnicity in America. Ethnic protest emerges as a means of ritually reaffirming the collective identity of that social arrangement, which is now being attacked, and as a more literal means of resisting this loss of control.

Neo-Ethnicity: The Last Quiver of Assimilation?

We return to the original question: What of the melting pot thesis? The control ethnics have exercised over American cities can be seen as part of the *persistence* of ethnicity, and the subversion of that control by the government and the rising political strength of blacks must be seen as part of its *demise*. Assimilation is more than the shedding of habits, customs and social identities. It is also the crumbling of the organizational manifestations of ethnic per-

sistence: the control of city politics taken earlier from the native Yankee-Protestants. While assimilation is by no means complete, this outburst of defensive ethnicity means ethnics are losing control of one of the social structures in which ethnic consciousness and power was institutionalized. The new ethnicity reflects weakness, not strength, and the demise of ethnic control over the political structures of their communities, not its persistence. In this sense, the original assimilation hypothesis is ironically supported by this appearance of ethnic solidarity.

REPLY TO LEVINE AND BERGESEN

Although Levine and Bergesen disagree regarding assimilation as a model of ethnicity, their principal criticisms of our paper are similar: for both of them, we focused too heavily on economic, ecological, and institutional explanations of ethnicity. For Levine, we omitted social interaction between individuals whose "social constructions" are said to have an important impact on the formation of ethnic identities. For Bergesen, we omitted political factors, particularly the social-psychological reaction of white ethnics to their loss of political influence. We accept their characterization of our paper as largely ecological. We were interested in identifying the structural relationships between the changing political economy of American cities and the formation and maintenance of ascriptive groups.

Levine's central hypothesis, that "ethnic identities as emergent phenomena arise through social interaction," appears reasonable to us. There is a long tradition of social psychology which has demonstrated the importance of social interaction for self-identification. We see no reason why these hypotheses do not apply to ethnic identities. We strongly suspect that structural conditions set the parameters within which the interaction takes place and within which the "social constructions" are generated. We suggest that the structural conditions are central to the formation of ascriptive groups, while social interaction between emerging groups—as well as interaction within any single group—may be central to the formation of personal identities.

Levine concludes his comment with the assertion that without the interactionist perspective, one "must rely on 'cultural' definitions of urban ethnic units, taking them as they are found, and assuming that their present form

existed 'since time out of mind.' " While he notes that we discussed the formation of the white Southern ethnic group in Chicago, he apparently failed to understand the major point of our paper. We concluded that rather than being a survival from other times and places, ethnicity may be best understood as a product of the American social structure. We came to this conclusion without the interactionist perspective.

In contrast to Levine's essay, which raises provocative research questions concerning the relationship between the political economy, social interaction, and the emergence of groups and personal identities, Bergesen's comment is based on a series of ahistorical assumptions concerning ethnicity, urbanization, urban politics, and opportunity structures. Apparently related to the ahistorical nature of his remarks is the misdirection of inquiry from the urban macro-structure to the defensive reactions of urbanites.

In commenting on a paper which emphasized the variable nature of ethnicity and which identified three forms of ethnic groups in contemporary cities, Bergesen writes: "We cannot speak of ethnicity as if it were one unified phenomenon. The highly *politicized* ethnic solidarity of the past decade is quite different from the notions of ethnicity as customs, religious practices, language, neighborhood networks and everything else one ordinarily means by being 'ethnic.' Yancey conceives of ethnicity in this way. . . ." We were relatively precise in our definition of ethnic groups. None of the elements of our definition are included in Bergesen's characterization of it.

Bergesen's critique of our paper is replete with ahistorical models of urban social structure. He suggests that recent federal efforts aimed at improving the level of social justice in cities has resulted in the unprecedented loss of local autonomy; he chooses to ignore the fact that the activities which have built cities—commerce, industry, and government—inevitably tie local areas to distant hinterlands. He assumes that local politics have been independent of external controls and relationships until the 1960s; he chooses to ignore such persuasive authors as Pirenne (1925), Duncan and Lieberman (1970), Vidich and Bensman (1958) and Warren (1963). He assumes that urban political structures have been static, remaining unchanged except for their ethnic coloration—Yankees, white ethnics and now blacks; he ignores the dynamic aspect of urban politics (Merton, 1957). He assumes that the position of blacks today is analogous to that of immigrants seventy years ago; he ignores the

differences in the structure of cities, in urban opportunities and the overriding and persistent fact of racial discrimination. Northeastern cities at the turn of the century were the centers of commerce and industry; some are now facing fiscal disaster.

Bergesen may be correct in his assertion that there has been an increase in the level of political and group consciousness among the urban white working classes. He may be correct in his assertion that this is related to the changing structure of urban politics. We are not convinced that it is possible to separate changes in urban politics from changes in urban ecological structures; neither are we as sanguine as he regarding recent federal intervention into local politics and the increased political power of blacks as *the cause* of solidarity among the white working class.

The most disturbing aspect of Bergesen's note is his assertion that the recent complaints of the urban working class are political in nature and not "simple ecology." Such an analysis avoids concern with the ecological constraints imposed upon the urban working class. It turns a social issue that is generated from structural conditions into an analysis of individual complaints. By contrast, the "simple" ecological perspective enables one to pursue the question of how structural location within complex societies encourages (or discourages) specific forms of organization and political action. In the case of the urban working class, it considers the fact that many ethnic communities were formed around expanding concentrations of industrial employment. That was over fifty years ago. Today these same communities are characterized by relatively old (and increasingly less competitive) industries or by vacated industrial shells. We don't claim to know *the cause* of the complaints of the Irish (and non-Irish) in South Boston, but we suggest that if they did not have common occupations, residential stability and common institutions, if they did not face similar economic structures, if they were not entrapped in urban neighborhoods experiencing industrial decline, then they would be less likely to behave as communities. It appears to us that the "new ethnicity" is a substantively different phenomenon from the "old ethnicity." To equate the two or to describe the new ethnicity as a reactionary movement is to ignore the economic structures from which it has emerged.

IS COMMUNITY ALIVE AND WELL
IN THE INNER CITY?

(COMMENT ON HUNTER, ASR
OCTOBER, 1975)

Hunter (1975) has presented data which he claims questions the widely held view that ecological processes, notably urbanization and "decline" of inner-city neighborhoods, entail a loss of community. Three dimensions of community are investigated:

1. community as a functional spatial unit meeting sustenance needs,
2. community as a unit of patterned social interaction,
3. community as a cultural-symbolic unit of collective identity.

Replicating a survey conducted in 1949 in an inner-city neighborhood, he finds, in 1974, that while use of local facilities (shopping, churches, movies, doctors, banking and employment) has declined, the level of informal neighboring (chatting, exchanging favors, visiting, etc.) has remained about the same, and the "sense of community" (identification with place as a distinctive area, measured by an attitude scale) has increased. He (p. 549) interprets this as an indication "that the hypothesized consequences of an ecological and functional increase in scale have not resulted in a social and cultural-symbolic loss of community in this area."

A question can be raised as to whether the indicators used adequately measure the dimensions of community selected for analysis. Definitions of community, and each of these dimensions, focus upon integrative mechanisms within differentiated wholes. The holistic char-

acter of the urban neighborhood is suspect, by definition. A community should be capable of meeting the full range of fundamental human needs (Arensberg, 1961; Konig, 1968; MacIver, 1937). By this requirement, the neighborhood studied by Hunter was not a community in 1974, nor was it when studied by Donald Foley in 1949. Only 17.0% of the respondents worked in the neighborhood in 1949 and only 11.4% in 1974. Most of the major institutional functions, such as employment, government and education, were organized on a city-wide basis. At both times, the relatively complete local society was the larger metropolitan field. That urban people interact casually with their neighbors and have an identity with their area of residence in the city is not surprising. The empirical literature has not suggested otherwise. But to take such as evidence of a unit of patterned social interaction or of a cultural-symbolic unit of collective identity is to exaggerate the meaning of the measures. The finding that neighboring and place identification were weakly related to use of local facilities in 1949 and in 1974 shows that these are neighborhood rather than community phenomena. With functional integration removed to the larger field, these measures simply show persistence of association among neighbors in common activities of household and family life.

Hunter also presents observations based on his field work to argue that movement into the area in recent years has been motivated in part by a search for community and that among residents there has been a conscious effort to create community. Many people moved into the area, according to Hunter, because they desired such characteristics of the area as cheap housing, an urban environment, a racial mix and proximity to the University of Rochester. Such reasons, we submit, have no necessary connection to community; they merely reflect values which make the area attractive to some people. Some people, as Hunter notes, were searching explicitly for community, but other motives appear to have been dominant. The attempt to create community, according to Hunter, is shown in the creation of a citizen's association, which was set up to deal with air and noise pollution from a nearby airport and to prevent "block busting." One of its main functions has been to attempt to attract white homeowners so as to maintain racial balance. Members tend to be older, more highly educated homeowners who have recently settled in the area. In brief, this appears to be a special interest organization intended to protect real estate investments. The fact that it sponsors occasional political rallies, fairs and celebra-

tions does not make it a community association. Special interest groups such as this, which exist in many cities, are unlikely to provide the multi-interest linkages and coordination necessary for community. Nor can a racial distribution be accepted as a measure of integration.

Community in the full sense that we should define it is, of course, rare in a metropolitan society; and Hunter's finding that inner-city residents still engage in friendly interaction and have a sense of identity with their neighborhood is evidence of persistence of a quasi-communal aspect of modern life. Perhaps that is all that is to be left of community in America—friendliness and awareness of living near one another.

REPLY TO LULOFF AND WILKINSON

I appreciate the comments of Luloff and Wilkinson as an opportunity to clarify a number of misconceptions—not only about my research, but about the concept of community itself. I think the major difficulty the authors have with my research is that they have attempted to define away what I consider to be an important empirical problem for urban sociology.

The authors begin by giving a "normative" definition of how community should be defined: "A community should be capable of meeting the full range of fundamental human needs" and, more explicitly about my research, they say "the relatively complete local society at both times was the larger metropolitan field." This is a holistic conception of community which, restated in the terms of my research, would say that all three dimensions of community (ecological, social and cultural) should be coterminous at the same scale.

However, precisely what I did was to treat each of these dimensions separately to test empirically whether or not, in fact, they were coterminous and to assess differences in the changes in these dimensions over time. The data show that the functional ecological community increasingly was operating at the expanded scale of the metropolitan field. The authors accept this finding but, with respect to the findings for the social and cultural dimensions, they begin to question the research's operational adequacy. "That urban people interact casually with their neighbors and identify with their area of residence," they say, is "not surprising." They add that these findings are an "exaggeration" of the meaning of "patterned social interaction" and "collective identity." First, I believe the findings were surprising in the persistence of community in the light of hypotheses to the contrary. Second, if these are not "patterned social interaction" and "collective identity," what are they? Where the authors err is in inferring that these are the *only* units of patterned social interaction and collective identity which these urban residents maintain. Nowhere do I imply this. It appears that the authors accept the findings of the ecological functional dimension of community because these fit their preconceptions of how community should be defined, but they do not accept the findings for the social and cultural dimensions because these findings do not fit their preconceptions.

Instead of accepting these findings, the authors attempt to define them away by maintaining that the local area I studied was a neighborhood, not a community. Elsewhere (Hunter, 1974; Hunter and Suttles, 1972), I have attempted to develop a less simplistic view of urban communities as a single-scaled phenomenon. A more inductive approach shows that urban residents live in a number of different scales of local communities ranging from the social block to the neighborhood, the local community and the expanded community of the urban region. Furthermore, different functions, activities and sentiments of residents are seen to vary systematically from level to level. In the modern metropolis, people simply do not live in a single community; but, rather, function in what I call a symbolic system of hierarchical communities. An individual's local communities will vary, not only throughout the life-span but even in the course of meeting his day-to-day life needs. I believe this multiple conception of community is closer to Robert MacIver's than is the single-scale, holistic conception the authors attribute to him. As MacIver (1970:30) says, "It will be seen that a community may be part of a wider

community, and that all community is a question of degree. . . . The one extreme is the whole world of men, one great but vague and incoherent common life. The other extreme is the small intense community within which the life of an ordinary individual is lived, a tiny nucleus of common life with a sometimes larger, sometimes smaller, and always varying fringe."

The authors also maintain that the community association in this area "*appears to be a special interest organization intended to protect real estate investments,*" and that "*special interest groups, such as this, are unlikely to provide multi-interest linkages and coordination necessary for community*" (italics added). However, as I point out in the article, this is but one of the association's important interests. The authors appear to dismiss the other activities as insignificant and irrelevant and, again by a selective reading and redefinition, this association becomes a special interest group. Nowhere do I maintain that the association is the community as the authors would imply; but, even by the authors' own criteria, it is a community association. It does provide multi-interest linkages and coordination within the community and, furthermore, it is a powerful political voice in representing the community across a diversity of interests with agents external to the community.

The most bald example of the authors' refusal to accept the findings that elements of community exist at the local scale is the opening line to their last paragraph where again they assert, by definition, that the problem does not exist: "Community in the full sense that we *should* define it is, *of course*, rare in a metropolitan society . . ." (italics added).

In concluding, the authors begrudgingly admit that perhaps I have documented some "quasi-communal" aspect of modern urban life. I think that "quasi-communal" has less to offer as a theoretical construct that may be linked to research than do the three dimensions of community defined for study in my article.

In their last sentence, the authors highlight what I think are also two prevalent misconceptions in the study of urban communities. They say: "Perhaps that is all that is to be left of community." This implies first, that contem-

porary communal forms are simply "residues" and second, that these residues are relatively insignificant. I would suggest that the significance or insignificance of these communal forms and their intersection with other spheres of modern life should be empirically assessed and not simply hypothesized into oblivion (Kornblum, 1974). Also, I would suggest that community is not simply a "residue" but, rather, that it is an emergent, socially-constructed reality (Suttles, 1972). I think it would be better for us to launch a series of empirical studies of the variety of communal forms and the processes of community formation and change rather than to debate the definition of community and then bemoan its predefined demise.

Finally, I would like to suggest that the authors consider more seriously the dynamics of community which were a major concern of my article. Their critique is couched in a static conception of community, while most propositions within urban sociology imply an inter-linked set of historical transformations of local communities and urban life. I believe the data and resources are available and all that is required is a clear and concerted effort by researchers to explore these transformations.

He is engaged in a broad program of longitudinal research into social strain, coping behavior and psychological distress. **JOYCE S. JOHNSON** is a program analyst who was at the University of Maryland at the time of this work. Ms. Johnson is currently working on the construction and evaluation of health and safety standards in occupational environments.

■ **MICHAEL K. MOCH** (Organizational Innovations) is Assistant Professor in the Department of Business Administration, College of Commerce and Business Administration, University of Illinois, Urbana. He is currently investigating the impact of position in various networks (e.g., status, influence, interdependence, friendship) on individuals' attitudes at work. This is part of a larger effort to reconceptualize organizational structure to better understand how structure constrains and channels beliefs, values and behavior. **EDWARD V. MORSE** is Associate Professor of Sociology at Tulane University and Adjunct Associate Professor in the Tulane School of Public Health and Tropical Medicine. His current projects include the study of program adoption of health care techniques in Latin America, the application of career concepts to the sociology of adulthood and the study of career paths of academic scholars.

■ **LYNNE G. ZUCKER** (Institutionalization and Cultural Persistence) is Assistant Professor of Sociology at the University of California at Los Angeles. She is currently conducting a laboratory experiment which explores the relationship between labeling theory and the ethnomethodological theory of typification. She also is designing research to explore the impact of formal organizations on other social institutions and relationships in non-organizational settings. The basic theoretical approach is developed specifically to apply to social policy and evaluation problems, such as occupational mobility in manpower training programs. She is coauthor (with Howard E. Freeman and Wyatt Jones) of the forthcoming *Social Problems: Causes and Controls* (3rd edition).

■ **ILENE NAGEL BERNSTEIN** (Societal Reaction to Deviants) is Assistant Professor at Indiana University where she has a joint appointment in the Department of Sociology and Indiana University Law School. She is continuing her research on the antecedents of criminal justice processing decisions for defendants in metropolitan state courts and working (with John Hagan) on a study of the social organization of criminal justice processing in federal courts across the U.S. Her most recent book (with Howard E. Freeman) is *Academic and Entrepreneurial Research: The Consequences of Diversity in Federal Evaluation Studies* (Sage, 1975). **WILLIAM R. KELLY** is a Ph.D. candidate in the Department of Sociology, Indiana University. His present research includes a cross-national analysis of fertility differ-

entials, and study of theoretical and empirical relations between violence and social change. **PATRICIA A. DOYLE** is a Ph.D. candidate in the Department of Sociology, Indiana University. Her current research addresses questions of theoretical and empirical relations between work behavior and sex role orientations.

■ **MARK ABRAHAMSON** (Patterns of Urban Dominance) is Professor and Head of the Department of Sociology at the University of Connecticut, Storrs. He is presently studying patterns of stratification in professional sports. His most recent book is *Functionalism* (Prentice-Hall, in press). **MICHAEL A. DUBICK** is Assistant Professor of Sociology at the University of Minnesota. He is examining the organization of the news media and how it is affected by the social organization of the city in which they are located.

■ **ROSS M. STOLZENBERG** (Fertility Expectations and Employment Plans) is Assistant Professor of Sociology at the University of Illinois, Urbana. His current research includes the study of structural features of occupations, labor markets and industries and their consequences for the socioeconomic achievement of individuals. **LINDA J. WAITE** is Assistant Professor of Sociology at the University of Illinois, Urbana. Her current research includes an analysis of the consequences, for a woman, of an early first birth. This study, which focuses on the impact of teen-age childbearing on a woman's educational attainment, labor market behavior and rewards, as well as marital stability and later childbearing, is being done at the Urban Institute with Kristin A. Moore. In addition, she is studying the development of career commitment and its consequences among young women.

■ **DAVID F. SLY** (Ecological Approach to Migration) is Associate Professor at the Center for the Study of Population, Institute for Social Research, Florida State University, Tallahassee. His current studies include how rural development programs affect patterns of urbanization, how variations in the ecological structure of metropolitan areas, cities, and rings affect patterns of growth (with Robert Weller), how population redistribution affects the personal energy consumption sector (with Wilbur Zelinsky), how population loss to metropolitan areas is related to the theory of ecological expansion, and the relations between food production, food availability and urbanization. His most recent book (with Sidney Goldstein) is *Patterns of Urbanization: Comparative Country Studies* (Dolhain, Belgium: Ordina Editions, 1976). **JEFF TAYMAN** is a Ph.D. candidate in the Department of Sociology, Florida State University, Tallahassee. His current research concerns the effects of the growth and expansion of metropolitan areas on commuting patterns and the effects of family health care programs on fertility.

■ **JACQUES DELACROIX** (Export of Raw Materials and Economic Growth) is Assistant Professor of Sociology at Indiana University, Bloomington. This paper is part of an ongoing project of quantitative assessment of diverse aspects of the sociology of economic development.

CHARLES C THOMAS • PUBLISHER

THE MALTREATED CHILD: The Maltreatment Syndrome in Children — A Medical, Legal and Social Guide (3rd Ed.) by Vincent J. Fontana, *New York Foundling Hospital, New York City*, and Douglas J. Besharov, *United States National Center of Child Abuse and Neglect, Washington, D. C.* Foreword by Mother Loretto Bernard. The Third Edition of this vital text presents the problems of child maltreatment; their nature, causes and extent; and the means to deal with them. Among the text's outstanding features are a statistical outline of child abuse, a discussion of social and medical manifestations and preventive measures, and a review of methods of differential diagnosis. '77, 176 pp., 11 il., \$12.50

CIVIL LITIGATION AND THE POLICE: A Method of Communication by Robert H. Sulnick, *Loyola Law School, Los Angeles, California*. The methods and research of this book are designed to show how law and social science, joined together, create the power and ability to functionally communicate with the policymakers in modern social institutions, specifically with the police. The book further shows that such a communication has the ability to cause the institution to change its policies. Contents include civil litigation, the police as a bureaucratic institution, police and authoritarianism, and the appellate courts and the power of the law. '76, 168 pp., \$10.75

OLDER PERSONS AND RETIREMENT COMMUNITIES: Case Studies in Social Gerontology by Jerry Jacobs, *Syracuse Univ., Syracuse, New York*. This is a comparative ethnographic study of three different kinds of retirement settings. Two of these settings are lower class urban public housing projects for the elderly (one of which is located on a university campus), while the third is a privately developed middle to upper class rural retirement setting. The study deals with the patterns of interaction which develop in these three settings, why they took the forms they did, the meanings of these interactions to the participants, and recommendations for altering these interactions. '75, 144 pp., cloth-\$10.50, paper-\$6.95

SENTENCING: Process and Purpose by Gerhard O. W. Mueller, *United Nations Crime Prevention and Criminal Justice Section, New York City*. Foreword by Ernest John Watts. Based on the premise that prison is an escape for both the criminal and society, this book deals with the process by which millions of Americans are sent to jail in the hope that society might thereby be made safer. The process and philosophy of sentencing are critically examined and alternatives to prison are presented. Following a description and evaluation of the goals of the present system, the author suggests ways to introduce new standards of treatments into the correctional process. '77, 228 pp., 2 il., \$14.50

CHANGING SEXUAL VALUES AND THE FAMILY edited by G. Pirooz Sholevar, *Hahnemann Medical College and Hospital, Philadelphia*. (22 Contributors) In demonstrating how changing sexual values affect different people, this book describes such changes as viewed by sociologists, anthropologists, family therapists, psychiatrists, social workers, psychologists and students. Topics of discussion include the family system and society, sexual problems in marital therapy, incest, changing female sexual values and the future family structure, symbolic sex in family therapy, and techniques of family therapy. '77, 192 pp., 5 il., \$11.75

WOMEN AND EDUCATION edited by Elizabeth Steiner Maccia, with Martha Ann Coleman, Myrna Estep and Trudy Miller Shiel, *all of Indiana Univ., Bloomington*. Many areas of education have pressed the female into passive attitudes toward her place in society. Only now is this trend beginning to change. This book is a step in this direction as it provides readings for assessment and analysis of the context, the teacher-learner relationship, and the curriculum of the education of women. Topics include sex roles in reading textbooks, schooling of tomorrow's women, how ideology shapes women's lives, portrayal of women in children's literature, and more. CRISIS IN AMERICAN INSTITUTIONS

Third Edition

Jerome H. Skolnick

University of California, Berkeley

Elliot Currie

Now in its third edition, this popular reader focuses on the institutional and systemic bases of social problems and disorders. The reader comprises 41 essays by noted experts that address themselves to an analysis of current realities, institutional failures and responsibilities, and prognoses for the future. The editors introduce each topical section with an essay providing historical perspective and sociological insight. This new edition retains the coherent organization, the economic/political orientation, and the intellectual integrity which have led to its wide adoption in the past. Instructor's Manual available.

Paper 586 pages 1976 \$7.95

SOCIAL PROBLEMS: THE CONTEMPORARY DEBATES

Second Edition

John B. Williamson

Boston College

Jerry F. Boren

Merrimack College

Linda J. Evans

Central Connecticut State College

This new edition retains the popular reader/text format of the first while incorporating new areas of debate that have gained national prominence since publication of the original: forced busing, affirmative action, gay rights, health care, and the relevance of a liberal arts education. In numerous cases, new readings have been added or substituted in debates which appeared in the first edition. As before, thoughtful and comprehensive essays precede each debate to introduce students to various analytical and theoretical models that sociologists might or do apply to the problem at hand. A manual of test questions is available.

Paper 473 pages February 1977 \$7.95

THE SOCIOLOGICAL PERSPECTIVE

Introductory Readings

Fourth Edition

Scott G. McNall

University of Kansas

THE SOCIOLOGICAL PERSPECTIVE was designed to help students understand what sociology is, which concepts are most significant in studying society, and what methods sociologists use to study society. The readings, organized within a systematic editorial framework, represent a wide range of theoretical and methodological perspectives. The new Fourth Edition has added economic and educational institutions to its section on institutions. Sections on doing sociology and interaction in everyday life have been added. The section on population now includes articles that show how changing attitudes about family size, etc., relate to women and work. Thirty-five of the fifty-seven articles are new. An Instructor's Manual is available.

CITY SCENES

Problems and Prospects

J. John Palen

University of Wisconsin, Milwaukee

CITY SCENES is a collection of articles that focus on the developing concerns of the '70s. Written by experts like Lee Rainwater, Mike Royko, Herbert Gans, Gerald Suttles, and Oscar Newman, the articles were chosen for their ability to inform, stimulate, and provoke reaction among students. The readings not only describe what is occurring in urban life today, but also offer the various authors' interpretations of what the "facts" mean in terms of policy. Extensive editorial commentary links the eight chapters, providing additional information and an overall perspective.

Paper 336 pages February 1977 \$6.95

THE RESEARCH CRAFT

An Introduction to Social Science Methods

John B. Williamson

Boston College

David A. Karp

Boston College

John R. Dalphin

Merrimack College

This text was designed for the introductory course in social research methods, primarily in departments of sociology, political science, social psychology, social work, and education. It is distinctive from competing texts in two important ways: First, it offers comprehensive coverage of research methods; Second, it emphasizes first-hand experience with each of the methods discussed through a series of exercises that can be carried out individually or in small groups.

Paper 468 pages January 1977 \$11.95

FAMILY IN TRANSITION

**Rethinking Marriage, Sexuality,
Child-Rearing, and Family Organization
Second Edition**

Arlene Skolnick

University of California, Berkeley

Jerome H. Skolnick

University of California, Berkeley

Since its publication in 1971, FAMILY IN TRANSITION has been one of the most influential books in the Marriage and Family field. Now there's a new Second Edition that retains the successful elements of the original, including its interest in the nature of the family, sexuality, and sex roles. There are new emphases, however, on structural and personal variations in household and life styles, on men's and women's roles, and on the social meaning of sexuality. An Instructor's Manual is available.

"... probably the most thorough methodological analysis in the survey trade ..."

—James A. Davis, Dartmouth College

SOCIAL INDICATORS OF WELL-BEING: Americans' Perceptions of Life Quality,
by Frank M. Andrews and Stephen B. Withey, Institute for Social Research, The University of
Michigan, Ann Arbor

"One judges the merit of a scholar's work on the basis of its significance for the solution of basic
problems in a given field and the feedback one receives about it from other scholars. On both
accounts the work of Andrews and Withey warrants very high marks."

—Alex C. Michalos, *Director, Social Indicators Research Program*

Concerned solely with perceptions of well-being, this book investigates how these perceptions are
organized in the minds of different groups of American adults, seeks valid and efficient means of
measuring these perceptions, and suggests ways these measurement methods could be implemented
to yield a series of social indicators. 455 pp., illus., \$25.00

ENVIRONMENTAL ASSESSMENT OF SOCIOECONOMIC SYSTEMS, edited by Dietrich F.
Burkhardt, Industrieanlagen-Betriebsgesellschaft mbH, Ottobrunn, West Germany, and William H.
Ittelson, University of Arizona, Tucson

This book presents an interdisciplinary approach to the assessment of the relationship between
social, economic, and technical subsets. It offers expert analyses by planners and research scientists
on effective and practical planning models for socioeconomic and socio-technical environmental
problems. The contributors examine the methodology of planning, prediction, and social response
to environmental impacts, and present in-depth case studies of socioeconomic systems throughout
the world. Volume 3 in the NATO Conference Series, Series III: Systems Science.

ESSAYS IN SOCIAL THEORY

STEVEN LUKES

From the author of *Emile Durkheim: His Life and Work* comes this solid collection
of essays on such recurrent problems in sociology as theory-making and evidence,
power and structure, and the alleged relativity of standards of rationality and valid-
ity. Two essays on Rawls's *Theory of Justice* and Nozick's *Anarchy, State, and Utopia*
lend the volume special interest. \$13.00

ESTRANGEMENT, ALIENATION, AND EXPLOITATION

A Sociological Approach to Historical Materialism

JOHN TORRANCE

By developing the fundamental concepts of estrangement, alienation, and exploita-
tion, this study aims to construct a formal sociological scheme that can plausibly be
seen as implicit in Marx's work and relevant to subsequent sociological theory. In
probing Marx's thought and relating it to that of later theoreticians, Torrance makes
plain the immense stimulus and resource Marx represents for modern sociology. \$22.50

COLUMBIA UNIVERSITY PRESS

Address for orders:

136 South Broadway, Irvington, New York 10533

“This is the most impressive book by Piven and Cloward yet...”

—MURRAY EDELMAN, Professor of Sociology, Columbia University

“This beautifully written book is the most exciting and important political study in years. Informative and analytical, it will long pose the vital questions for political science, political sociology, and social welfare studies...It challenges the received wisdom about reform and social change. In particular, the discussions of the civil rights and welfare rights movements are gems. This book is essential reading.”

—S.M. MILLER, Chairman, Department of Sociology, Boston University

“A powerful and persuasive debunking of the conventional wisdom of the Left, forcing us all to rethink once more how American society can become more egalitarian...This book may turn out to be the most memorable retrospective on the events of the 1960s...*Regulating the Poor* is already a classic; *Poor People's Movements* will surely become one as well.”

—HERBERT GANS, Professor of Sociology, Columbia University

POOR PEOPLE'S MOVEMENTS

WHY THEY SUCCEED, HOW THEY FAIL

PANTHEON

Our 35th Year

201 E. 50th St., New York, N.Y. 10022

HOUGHTON MIFFLIN **UPDATE:**

THE FAMILY, SOCIETY, AND THE INDIVIDUAL Fourth Edition

William M. Kephart, University of Pennsylvania
1977/546 pages/Instructor's Manual
Contemporary, revised, expanded, and visually attractive, the new Kephart has optimum appeal for students. "The Changing Status of Women" and "Alternative Life Styles" are two of many new chapters.

UNDERSTANDING SEXUAL INTERACTION

Joann S. DeLora, San Diego State University; Carol A. B. Warren, University of Southern California; with contributions by Carol Rinkleib and Douglas Kirby
1977/642 pages/Instructor's Manual
Provides a comprehensive overview of the field of human sexuality. Covers latest research findings in both behavioral science and physiology.

SOCIAL PSYCHOLOGY **The Theory and Application of Symbolic Interactionism**

Robert H. Lauer and Warren H. Handel
both of Southern Illinois University at Edwardsville
1977/467 pages/Instructor's Manual
Provides an introduction to social psychology from a symbolic interactionist perspective designed to give students materials for understanding human behavior and the stimulus to use those materials for analyses.

STATISTICAL REASONING IN SOCIOLOGY Third Edition

John H. Mueller; Karl F. Schuessler, Indiana University; Herbert L. Costner, University of Washington
1977/544 pages/Solutions Manual
A careful revision of the widely used and highly respected introduction to applied social statistics. Emphasizes intuitive understanding of statistical reasoning rather than mathematical derivations.

MANNY

A Criminal-Addict's Story

Richard Pearson Rattig; Manuel Julio Torres; Gerald R. Garrett, University of Massachusetts, Boston
1977/264 pages/paper
An autobiographical account of a criminal-addict career covering one individual's experiences with juvenile gangs, drug addiction, prisons; includes chapters that relate theoretical literature and perspectives to the subject's life.

POPULATION **The Dynamics of Demographic Change**

Charles B. Nam, Florida State University
Susan O. Gustavus, University of Cincinnati
1976/363 pages

THE AMERICAN CLASS SYSTEM: An Introduction to Social Stratification

Daniel W. Rossides, Bowdoin College

HARPER PAPERBACKS

HAROLD R. ISAACS

Idols of the Tribe *Group Identity and Political Change*

"This is a splendid book, doing for the subject of group identity what Erikson has done for individual identity. Brilliantly written, it synthesizes a vast body of material and speaks directly to a central problem of our time: ethnicity. Poignantly, Isaacs deals with the dilemmas of universality and particularity and their opposing tugs on our hearts and minds. It is a book written out of deep personal experience and profound intellectual reflection."

—BRUCE MAZLISH
CN/483 \$4.50

PAUL ROBINSON

The Modernization of Sex

Havelock Ellis, Alfred Kinsey, William Masters and Virginia Johnson

"This book is a judicious and—a miracle in such matters—witty account of the work of four 20th-century students of sex. . . . One may argue that sexual practices change in any case, without formal thinking about them, but it seems indisputable that the people [Robinson] has studied have helped the ethos take shape. To cut through the mists surrounding their findings and propositions isn't the easiest labor, and Robinson has done the job with admirable precision."

—RICHARD GILMAN, *The N.Y. Times Book Review*
CN/548 \$2.95

ALFRED J. KAHN and
SHEILIA B. KAMERMAN

Not for the Poor Alone *European Social Services*

"An absorbing first-hand appraisal of innovative government programs that have developed in Western Europe over the past several decades to improve the quality of life. Home health care in England, housing for the aged in Sweden, and government-subsidized vacations in France are representative of the topics presented. The study is balanced, nonemotional, well written, and judiciously researched."—*Library Journal*

"The descriptions may inspire those fighting for improved human services by showing what specific program ideas could be implemented on a national level. They also demonstrate how irrelevant are suggestions of loss of individual freedom if similar programs were to be adopted in the United States. . . ."

—*American Journal of Orthopsychiatry*

Sociology 1978

INTRODUCTION TO SOCIOLOGY, 3rd Edition

Mavis Hiltunen Biesanz; John Biesanz—Wayne State University

Well-written, extremely readable revision of successful text stresses basic concepts and principles, uses cross-cultural data to put study of American society into broader perspective. New sections on sex roles and political and economic institutions. Revised chapters cover the family, deviance, culture, race and stratification, urban life, population, social change, and modernization. Teaching aids include: Workbook, Test Item File, Instructor's Manual.

1978

720 pp. (est.)

Cloth \$12.95

THE SOCIOLOGY OF SOCIAL PROBLEMS, 6th Edition

Paul B. Horton—Western Michigan University

Gerald R. Leslie—University of Florida, Gainesville

Comprehensive coverage of major social problems includes systematic application of three approaches — social disorganization, conflict of values, and personal deviation. Analyzes the role of multinational corporations in the disruption of U.S. and world economic systems. Chapter on Interpretation of Data is designed to enable students to weigh evidence for themselves. Instructor's Manual and Study Guide available.

1978

768 pp. (est.)

Cloth \$14.95

INTRODUCTORY STATISTICS FOR SOCIOLOGY

Judith D. Handel—University of Missouri, St. Louis

Introduction to behavioral science statistics covers a variety of descriptive and inferential statistics. Detailed background chapters provide the reader with a firm math foundation — text assumes no mathematics beyond high school algebra. Attention is focused on deciding which statistical techniques are appropriate for the data available, applying those techniques and interpreting and presenting the results. Sociological examples aid in understanding the sociological uses of statistics—randomness is illustrated by the draft lottery; weather forecasting introduces the subject of confidence intervals; binomial distribution is demonstrated by a study of the racial composition of juries. Teacher's Manual available.

1978

432 pp. (est.)

Cloth \$14.95

FUNCTIONALISM

Mark Abrahamson—University of Connecticut

Brief overview clarifies the development of functionalism with special attention to sociology and anthropology. Examines many basic assumptions of the perspective and the controversies they have generated. Proposes procedures by which the value of functional interpretations can be assessed.

1978

144 pp. (est.)

Paper \$5.95

INEQUALITY AND STRATIFICATION IN THE U.S.

Robert A. Rothman—University of Delaware

Systematic and up-to-date analysis of inequality and social stratification with special emphasis on the American case. Considers sex, occupational, class, and racial/ethnic stratification. Sources and consequences are explored in this analytic core text, rather than relying on descriptions of the distribution of inequality.

1978

200 pp. (est.)

Paper \$6.95

INFORMAL GROUPS: AN INTRODUCTION

Stephen R. Wilson—Temple University

Overview of both sociological and social psychological literature pertaining to small groups. Utilizes a sociological perspective organized around the concept of solidarity. Particular emphasis given to studies of informal groups in natural settings.

1978

400 pp. (est.)

Cloth \$13.95

AN INTRODUCTION TO POLITICAL SOCIOLOGY

Anthony M. Orum—University of Texas, Austin

Comprehensive review of major topics in political sociology integrates theories with empirical studies from the fields of sociology and political science. Abstract ideas are illustrated with concrete references to American politics.

1978

368 pp. (est.)

Cloth \$13.95

THE SOCIOLOGY OF EDUCATION

Ann Parker Parelus—Rutgers College; **Robert J. Parelus**—Douglass College

Overview of the subject utilizes two major theoretical approaches — consensus and conflict theory. Coverage includes: historical background of contemporary issues, discussion of policy issues and alternatives, cross-cultural studies.

1978

400 pp. (est.)

Cloth \$12.95

MEDICAL SOCIOLOGY

William C. Cockerham—University of Illinois, Urbana

Up-to-date overview of the field discusses the major theories and research of the social behavior of people as it relates to medicine and medical practice. Incorporates topics relevant to today's medical sociologists — not available in other texts.

1978

400 pp. (est.)

The Maoris of New Zealand

Rautahi

JOAN METGE

*Professor of Anthropology and Maori,
University of Wellington, New Zealand*

First published in 1967 and now available in a fully up-dated, revised edition, this classic work was described by the *Guardian* as 'the most valuable study of the Maori to appear since Sir Peter Buck's epic work . . . it is packed with the fruits of long field-work among these gregarious, spontaneous and utterly civilized people'.

Illustrated \$17.95

People of the Mediterranean

An Essay in Comparative Social Anthropology

J. DAVIS

University of Kent, Canterbury

'This fascinating, learned and well-written book . . . bring[s] together what we know from mainly British and French anthropology about the lives of mainly the poorest and most marginal folk living more or less near these shores, and then subject[s] the data to close comparative analysis.' — *Economist*

Library of Man \$14.00

The Social Anthropology of Radcliffe-Brown

Edited by ADAM KUPER

*Professor of African Anthropology,
University of Leiden, Netherlands*

A.R. Radcliffe-Brown (1881-1955) was one of the first professional anthropologists, a pioneer who established what he called scientific, comparative sociology in the face of the entrenched traditions of ethnology and social evolutionism. Adam Kuper believes that Radcliffe-Brown and his ideas are still a living force in social theory, and here provides a selection of his best work.

A Dictionary of the Social Sciences

HUGO F. READING

Defining over 7,500 terms, the dictionary covers all the social sciences, including essential terms from subjects peripheral to the social sciences. As concise as possible without loss of meaning, the definitions are interrelated with terms defined elsewhere in the dictionary, thus giving the work a logical unity.

\$7.95, *paper* \$3.50

The Sociology of Secularisation

A Critique of a Concept

PETER E. GLASNER

Australian National University

The author's main aim is to place sociological discussions of the secularisation process within a theoretical framework. He explores the variety and depth of discussions in the work of a wide range of social theorists, and shows that the sociological myth of secularisation lacks a theoretical base. He therefore seeks to ground secularisation in theory, and offers a fundamental, methodological critique of the concept of secularisation.

International Library of Sociology \$11.00

Philosophical Foundations of the Three Sociologies

TED BENTON

University of Essex

Offering a critical evaluation of empiricist and positivist theories of knowledge, the book investigates some classic attempts at using empiricism and positivism to provide the philosophical foundation for a scientific sociology. The author discusses the Kantian critique of empiricism and goes on to investigate the adequacy of post-Kantian arguments from Rickert, Weber, Winch and others, concluding with an attempt to establish the possibility of a materialist and realist defence of the project of a natural science of history.

International Library of Sociology \$11.95

Class, Race and Gold

A Study of Class Relations and Racial Discrimination in South Africa

FREDERICK A. JOHNSTONE
Memorial University, Newfoundland

'This important study analyses the structure and history of class relations in South Africa, concentrating upon the gold mining industry during the eventful years 1910-1926. It substantially extends one's comprehension of the 1922 revolt [and provides a] rigorous elucidation of the relationship between class rule and racial discrimination.'

— Colin Blundy, *New Society*
International Library of Sociology \$15.25

Race and Suicide in South Africa

FATIMA MEER
University of Natal

'Through careful scrutiny of official documents and case studies, Meer offers an analysis of suicide in the Durban area from 1940 to 1970... Meer suggests that, contrary to the views of Durkheim and others, suicidal behaviour "does not conform to certain universal principles but responds to particular social conditions".'

— Winifred Lambrecht, *Library Journal*
International Library of Sociology \$15.50

Language, Education and Social Processes in a Gaelic Community

KENNETH MacKINNON

Hatfield Polytechnic

Foreword by Professor Basil Bernstein

Concentrating on the bilingual situation on the island of Harris, off the North-West coast of Scotland, the author shows how the everyday face-to-face process of language can help to explain the wider social setting of values, culture and the relationship of local to wider social structures. 'Will be valuable to sociologists outside the area and to teachers and planners within it.'

— Sara Erskine, *The Times Educational Supplement* paper \$10.95

Urban Housing in the Third World

GEOFFREY K. PAYNE

School of Architecture, Architectural Association, London

Geoffrey Payne asks whether recent changes in attitudes towards low-income housing in the Third World have gone far enough in realizing the urban dimension of housing problems and the issues of resource allocation and accessibility that are involved. He examines the existing concepts of housing and planning and the assumptions upon which they are based, and suggests alternatives.

Published jointly with Leonard Hill, London 80 illustrations \$18.75

Leisure and the Changing City 1870-1914

H. E. MELLER

University of Nottingham

'She is particularly well qualified to write about Victorian cities [and] moves naturally and easily from urban history to urban sociology (on both sides of the Atlantic)... In this interesting and well organised book she draws most of her facts from Bristol and her theories from elsewhere. She is refreshingly frank about this.'

— Asa Briggs, *New Society*
illustrated \$18.75

Centrality and Cities

JAMES BIRD

Professor of Geography, University of London

Synthesizes the many approaches to the study of the city, including its distant past and its future. The author sees centrality as a mental projection on to space, and this leads to extended discussion of the origin of centres that develop into cities, the evolution of their central areas, and the contrast between centres and peripheries.

POLICE IN A TIME OF CHANGE

John J. Broderick, Stonehill College

Avoiding the use of sociological jargon and making copious use of field note throughout, this high-interest text describes various police personalities and their sociological styles. It explores relationships both within police departments and between department members and the public. The text's emphasis on typical daily police problems and the need to professionalize law enforcement makes for lively class discussion by sociology students, future police personnel, and practicing law enforcement officers. Included are questions for discussion and a bibliography. 256 pages, paperbound, \$5.95

Forthcoming

SEX ROLES AND PERSONAL AWARENESS

Barbara L. Forisha, University of Michigan, Dearborn

Presenting sex roles from the sociological, psychological, and biological perspectives, this text provides examples by means of intriguing case histories carefully integrated into the text. Each chapter offers a summary, an exercise that encourages the student to apply the chapter content, and reference notes. Glossary and bibliography. 380 pages, paperbound, approx. \$6.95, February 1978

CONTEMPORARY TOPICS IN URBAN SOCIOLOGY

edited by Kent P. Schwirian, The Ohio State University

Nine chapters – each an original statement by a specialist – are grouped under the headings "The Emerging Metropolis," "Organization of the City," and "Problems, Politics, and Planning." Useful either as a basic text or as a reader, this work is flexible in its sequencing of topics. 660 pages, cloth, \$12.95

Two Basic Texts

Sociology: Human Society

Melvin L. DeFleur, The University of New Mexico
William V. D'Antonio, The University of Connecticut / Lois DeFleur Nelson, Washington State University

Second Edition

◆ Diamond Printing

September 1977, 652 pages, illustrated, paperback, approx. \$11.95

Second Brief Edition

January 1977, 461 pages, illustrated, paperback \$9.95

Sociology: Human Society continues to be the most current and comprehensive introduction to sociology available. In the **Diamond Printing**, extensively revised Chapter 11, "Demographic Change," shows students the dramatic changes taking place in world population patterns. Other important new features include: a section on careers in sociology, a four-page photo essay on changing sex roles, several new Viewpoints and revised Tools of Sociology, and extensively updated tables, statistical presentations, and citations of sociological research. The **Brief Edition**, a compact text focusing on the basics of sociology, includes a significant chapter on "Social Institutions in a Changing Society."

Complete Supplementary Program

The **Instructor's Manual** includes course outline, sociological games for classroom use, plus major themes, key terms and concepts, discussion questions, and bibliographies for each text chapter. The 1543 **Test Items** are page-referenced to the text and labeled by level of difficulty.

Research and Review, students' guide, supplies six sociological games, research projects, key ideas for review, and self-review questions with answer key, page-referenced to the text. **Personalized System of Instruction** provides study questions and optional exercises for mastery of text material at students' own, self-determined pace (with Instructor's Manual).

Exciting New Reader

Sociology for Our Times

Gerald L. Sicard, Miami-Dade Community College
Phillip Weinberger, Waynesburg College

Forty-one lively selections cover a broad range of interesting topics, showing students the relationship between sociology and contemporary life. A correlation chart shows how chapters of leading texts correspond to the reader. January 1977, 329 pages, illustrated, paperback \$5.95

Two New Comprehensive Books

Social Problems

Dennis E. Poplin,
Murray State University

Social Problems provides a sound, basic, and highly readable introduction to social problems in contemporary society. Each chapter analyzes a specific social problem in terms of its nature and extent, its causes, and potential methods of amelioration. Two introductory chapters help students understand social problems from the perspectives of deviant behavior, structured inequality, and institutional crises.

Extensive study aids—chapter outlines, summaries, discussion questions, glossaries, and annotated bibliographies—Increase students' understanding. One-page human interest features show students how social problems can and do affect them personally. Abundant photographs add interest and visual reinforcement of important textual concepts.

Examine in November. January 1978, approx. 512 pages, illustrated, hardbound, approx. \$11.95, with Instructor's Resource Book

Social Problems

**Institutional and
Interpersonal Perspectives**

Kenneth Henry,
Fairleigh Dickinson University

Fifty classroom-tested articles—including cross-cultural entries and topics rarely found in similar readers—explore fifteen contemporary social-problems subject areas.

A simple method suggested in the **Introduction** helps students develop institutional analysis skills, and an original article by the author offers three kinds of theory for students to use in analyzing any social problem from the personal to societal levels. A chart correlates the reader with leading social problems texts.

Examine in October. January 1978, approx. 540 pages, paperback, approx. \$6.95, with Instructor's Manual

New and Significant from Basic Books

WORLDS OF PAIN

Life in the Working-Class Family

Lillian Breslow Rubin

"Compassionate and sensitive, Miss Rubin forces us to look at the underside of American life in a new way. . . . She describes a grim world of work without pleasure, of marriage without communication, of sex without love, of aspiration without fulfillment."—*Alden Whitman, The New York Times* *Cloth \$11.95*

New Paperback Edition \$4.95

BEHAVIOR AND MISBEHAVIOR

Explanations and Non-Explanations

Nigel Walker

One of the world's leading criminologists shows why the explanations of social science so often fail to define "criminal," "deviant," or "abnormal" behaviors that are for the most part unexpected and unpredictable. Drawing on his own experience as well as on numerous examples from criminal law and literature on deviance, Professor Walker demonstrates that seeking a general theory to explain all forms of crime—or even all forms of deviance—is futile. *\$10.00*

FATHERS, MOTHERS, AND SOCIETY

Toward New Alliances

Rhona & Robert Rapoport and Ziona Strelitz

With Stephen Kew

A thorough review of family situations throughout history, focusing on the role and needs of parents. Describing the issues surrounding the relation of parents' and children's preoccupations and requirements at different stages of the life cycle, the authors propose a new, more varied, flexible, and open model of family living. *\$15.00*

HAVEN IN A HEARTLESS WORLD

The Family Besieged

Christopher Lasch

In a series of fascinating chapters on the evolution of American attitudes toward the family, one of our leading social historians shows why the family as an institution is becoming less and less capable of providing the refuge of love and decency in a cruel and heartless world. *\$15.00*

BASIC

BASIC BOOKS INC.

10 EAST 53RD ST, NEW YORK 10022

OXFORD

Human Nature, Class, and Ethnicity

MILTON M. GORDON, University of Massachusetts, Amherst. □ The centerpiece of this collection of essays is a provocative exposition of a theory of human nature, a subject which all social scientists and social practitioners must address, Professor Gordon contends. Drawing on a lifetime's work, he first surveys the views of important sociologists then presents his own theory, taking into account both biological predispositions and the social and environmental forces which interact with them. Remaining papers highlight the author's significant analytic work in racial and ethnic group relations, assimilation and pluralism, social stratification, and marginality.
January 1978 256 pp. cloth \$12.95
paper \$3.50

Masters of Social Psychology

Freud, Mead, Lewin, and Skinner
JAMES E. SCHELLENBERG, Indiana State University. □ The lives of these modern masters are explored here to show a direct correlation between their life experiences and their subsequent theories. The author examines the interrelationships and limitations of their respective theories and shows their profound impact on contemporary social psychology and everyday life.
January 1978 136 pp. cloth \$9.95
paper \$2.00

Sex Roles

Biological, Psychological, and Social Foundations
SHIRLEY WEITZ, The New School for Social Research. □ "This splendid book provides a lively and scholarly integration of what is known about sex roles...A remarkable and important achievement!"—Marcia Guttentag, Harvard University
1977 256 pp. cloth \$10.00
paper \$5.00

Environmental Choice, Human Behavior, and Residential Satisfaction

WILLIAM MICHELSON, University of Toronto. □ "A highly significant benchmark study which brings a whole new perspective to research in residential mobility....Rich in empirical content and penetrating in depth....This book will clearly become a classic reference for people working on housing choice in the urban scene."—F. Stuart Chaplin, Jr., University of North Carolina, Chapel Hill. "One of the few studies ever done which really permits us to single out the effects of housing on social life....His conclusions have immediate policy implications."—Charles Tilly, University of Michigan

Power and Ideology in Education

Edited by **JEROME KARABEL**, Harvard University, and **A.H. HALSEY**, University of Oxford. □ Thirty-seven articles, many of them appearing here for the first time, provide an interdisciplinary approach to the understanding of educational institutions in modern society. The readings, contributed by historians and anthropologists as well as by sociologists and economists, together create a synthesis of the variety of theoretical perspectives and methodological approaches now competing for attention in educational research. Also noteworthy is the extensive introductory essay by the editors which presents an original and long overdue assessment of developments in the field. "Most provocative, potent collection of essays on ideology I've seen—well balanced, comprehensive!"—Michael Auer, California State University, Northridge

EXPLAINING CRIME

Gwynn Nettler, The University of Alberta

Now in its second edition, this important text reviews competing perspectives on crime in terms of their central concepts, their factual grounding, and their predictive powers. It is the only *critical* summary of the variety of explanatory ideas on crime current among social scientists. This new edition has been greatly expanded, revised, and updated, including new chapters discussing economists' views of crime-production and a new chapter that evaluates the "labeling" (societal reaction) school.

1978, 464 pages, \$8.95

Instructor's Manual available

MODERN CRIMINAL JUSTICE

Peter W. Lewis, University of South Florida

Jack Wright, Jr., Loyola University

This comprehensive text was designed to give the beginning student an overview of the criminal justice system. It includes in-depth treatment of important topics not usually covered in introductory criminology texts, such as organized crime, victimless crime, the nature and extent of street crime, the grand jury, the constitutional rights of offenders, the bail system, and the stages of a criminal trial.

1978, 416 pages, \$13.95

EFFECTIVE CASEWORK PRACTICE

Joel Fischer, University of Hawaii

In its scope, its depth, its currency, its relevance, this book is a landmark in the development of social casework. It uses an empirically based eclectic orientation to provide (1) guidelines for evaluating the jumble of existing clinical approaches, (2) a framework for selecting the most effective approach, (3) models for integrating such an approach in practice, and (4) a description of current approaches that have proved most effective.

1978, 480 pages, \$12.95

Prices subject to change.

**SOCIOLOGY: Change
and Continuity**

Carol A. B. Warren,
University of Southern California

Written for introductory sociology students, this compelling text focuses on those areas of social life which are continuous over time, and on those which represent change: *social problems and transition.* 1977/\$12.95

**CRIMINOLOGY: Power,
Crime, and Criminal Law**

**John F. Galliher and
James L. McCartney,** *both of the
University of Missouri*

An analysis of the criminal justice system that discusses criminal behavior mainly as a political and cultural product created by powerful interest groups and their representatives: *legislators, police, and judges.*

1977/\$13.95

**PARENTS IN MODERN
AMERICA, Third Edition**

E. E. LeMasters,
University of Wisconsin
(paperbound)

Updated to include social change of the 1970's in almost every chapter. Examines the American mother and father, parents, mass media, and the youth peer group, among others.

1977/\$5.95

**SOCIOLOGICAL
RESEARCH: Philosophy
and Methods**

Henry L. Manheim,
Arizona State University

Presents a unique combination of the philosophical assumptions underlying any research activity, and the practical methods of doing research in the social sciences.

The Human Condition: A Continuing Drama

What makes HUMAN SOCIETIES different from other sociology texts? Its unique and exciting approach. The combined effort of a poet and a distinguished sociologist, HUMAN SOCIETIES is more than a glossary of concepts and definitions. It examines from prehistory to the present the evolution of human societies as a dramatic progression filled with crisis and turmoil. And by exposing students to the nature of past social change, it helps them prepare for the future.

Human Societies:

AN INTRODUCTION
TO MACROSOCIOLOGY,
Third Edition

Gerhard Lenski
Jean Lenski

Now the third edition of
HUMAN SOCIETIES
offers even more.

Most chapters have been rewritten and updated. Special attention is paid to the changing role of women and youth in society. There is a new section comparing biological and sociocultural evolution, and the comparisons between socialist and capitalist societies have been enlarged and updated.

Drawing from many disciplines for special insights and comparisons, HUMAN SOCIETIES offers effective and informative support for the instructor by providing a complete and stimulating view of macrosociology.

Available for examination

MARRIAGE AND FAMILY: BACKGROUND WITH UNDERSTANDING

Helping students with decisions about their personal lives can be one of the most trying yet rewarding tasks in higher education. These excellent texts offer invaluable insights and a strong academic foundation in the study of marriage and family.

MODERN MARRIAGE

 Eighth Edition

Henry A. Bowman,
University of Texas, and
Graham B. Spanier,
Pennsylvania State University

Bowman and Spanier's *Modern Marriage*—the eighth edition of a popular and authoritative text—combines Dr. Spanier's current research and counseling expertise and Dr. Bowman's forty years of teaching experience and field work. Various value-laden issues such as abortion, contraception, and marriage alternatives are treated carefully but completely. And other topics—both current and traditional—receive complete coverage as well. No other text offers such an effective combination of current insights, research, and decades of definitive field work. Available January, 1978; 512 pages, \$13.95

prices subject to change

PERSONAL RELATIONSHIPS: AN APPROACH TO MARRIAGE AND THE FAMILY

Ernest J. Green,
Prince George Community College

Green's *PERSONAL RELATIONSHIPS* puts the questions of marriage and relationships in a sociological context, enabling students to approach their closest human contacts with intelligence and knowledge. It offers a solid theoretical background of social issues and cultural trends—yet touches the personal experiences of almost every student.

Available December, 1977;
448 pages, \$12.95

Instructor's manuals are available
for both texts.

NEW FOR

THIS LAND OF PROMISES

The Rise and Fall of Social Problems In America

Edited by Armand L. Mauss, Washington State University; and Julie Camille Wolfe, University of Montana

A stimulating collection of twenty-five articles structured around a central theoretical perspective: that social movements are closely related to, and in some sense reinforce, social problems. The articles

range over problems of inequality, crime and sex, alcohol and drugs, political protest and the environment. The author-editors have prepared an extensive general introduction outlining their theoretical stance, introductions for each section and an epilogue.

452 pages/1977/paperbound, \$5.95

Second Edition

CORRECTIONAL INSTITUTIONS

Edited by Robert M. Carter, Daniel Glaser, University of Southern California; and Leslie T. Wilkins, State University of New York, Albany

This well balanced introduction to corrections comprises thirty-eight articles — of which twenty-seven are new to this edition — that cover the history and current status of prisons and prison systems, with particular emphasis on the problems of the

inmate. While retaining the structure of the first edition, this new edition stresses new approaches to correction, including community programs and innovative programs within prisons.

571 pages/1977/paperbound, \$7.95

Lippincott

ESSENTIAL STATISTICS FOR SOCIAL RESEARCH

Michael A. Malec, *Boston College*

Designed for students with limited mathematical background, this concise text provides enough of the basic matter of statistics to enable them to read sociological literature with some appreciation of the

function and significance of statistics. The content of this helpful book is limited to those statistics regularly used by sociologists.

235 pages/1977/paperbound, \$7.95

Fifth Edition

MARRIAGE AND FAMILY DEVELOPMENT

Evelyn Mills Duvall, *Family Life Consultant*

Completely rewritten and updated, this new edition includes data and findings from the latest research in the areas of marriage and family. New material includes such topics as: alternative forms of marriage; marriage contracts; sex differences and gender roles; marital options;

changing sexual attitudes and behavior; death of family members; dissolution of marriage; social change; and racial and ethnic differences. The life-cycle approach has been retained; keyed references, tables and charts amplify the text.

559 pages/1977/clothbound, \$12.95

OFFICIAL DEVIANCE

Readings in Malfeasance, Misfeasance, and Other Forms of Corruption

*Edited by Jack D. Douglas, University of California, San Diego;
and John M. Johnson, Arizona State University*

Comprehensive and up-to-date, the articles in this collection range over sociological analyses, government reports, historical and journalistic accounts, and comments by participants. Three initial articles define political corruption and show how criteria vary for defining corrupt

behavior in different times and societies. Coverage includes Watergate, CIA and FBI scandals, the NYC fiscal crisis, Kent State, Attica, and Washington lobbying. Each section has a brief introduction, and the last section offers proposed solutions to problems of official deviance.

396 pages/1977/paperbound, \$5.95

FAMILY STRUCTURE AND INTERACTION

A Comparative Analysis

Gary R. Lee, *Washington State University*

In this book the author demonstrates how comparative research has contributed to theory development in the sociology of the family. The focus throughout is on knowledge about family structure and behavior which has been generated, refined or ex-

tended by comparative research. Organization is topical, rather than systemic, with the objective of explanation rather than description. Controversial topics include premarital relations, sex roles, and the relationship of roles to conjugal power.

POLITICAL LANGUAGE

WORDS THAT SUCCEED AND POLICIES THAT FAIL

By MURRAY EDELMAN

A Volume in the INSTITUTE FOR RESEARCH ON POVERTY MONOGRAPH Series

Political Language: Words That Succeed and Policies That Fail examines the role of everyday language, governmental rhetoric, and professional language in creating dubious beliefs about the causes, nature, consequences, and remedies for poverty and related social problems. Incorporating recent social science concerns with phenomenology and structuralism, the book analyzes the nature and dynamics of complex cognitive structures engendered in public officials, professionals, administrators, and the general public through recurring cate-

gorizations, metaphors, metonyms, and syntactic structures. The focus is on the emergence and change of political cognitions that are nonempirically based and on the consequences for public policy of reliance upon symbolically engendered perceptions and beliefs. Considerable attention is given to the role of the helping professions. The analysis helps us understand the reasons governmental and professional actions contribute to poverty and related social problems while trying to ameliorate them.

NETWORKS AND MARGINALITY

LIFE IN A MEXICAN SHANTYTOWN

By LARISSA ADLER LOMNITZ

Translated by Cinna Lomnitz

A Volume in the STUDIES IN ANTHROPOLOGY Series

This book, a revised translation of *¿Cómo Sobreviven los Marginados?* (Siglo XXI, Mexico City, 1976), presents a detailed study of the social and economic structure of a Mexico City shantytown based on repeated house-to-house surveys and an extended period of participant observation. Using a combination of anthropological and sociological field methods, the author demonstrates that migration patterns, residential patterns, and occupational patterns all point

to the overriding importance of social networks as an underlying mechanism of economic survival. The findings in this book are discussed in the general framework of the economic and social evolution of Mexico, with particular attention to the effects of industrialization, rural-urban migration, and the differentiation of the urban poor into an industrial proletariat and a marginal sector having no access to the urban industrial economy.

1977, 248 pp., \$18.00/£12.80 ISBN: 0-12-456450-X

OCCUPATIONAL PRESTIGE IN COMPARATIVE PERSPECTIVE

By DONALD J. TREIMAN

A Volume in the QUANTITATIVE STUDIES IN SOCIAL RELATIONS Series

This monograph offers a definitive cross-national comparison of occupational prestige hierarchies and, as such, will be of interest both for its theoretical contribution and for its utility to research workers. Analyzing data from 60 nations ranging from highly industrialized places like the United States to such places as Nigeria, Thailand, and New Guinea, the author shows that a single world-wide prestige ordering exists which is relatively unaffected by local variations in occupational evaluations. To explain the

world-wide uniformity in occupational evaluations, a structural theory is proposed which argues that the division of labor creates inherent differences between occupations in the power they exercise, and that power begets privilege, and power and privilege beget prestige. An alternative theory, that the world-wide uniformity arises from the diffusion of a Western European pattern of occupational evaluations, is considered and rejected.

1977, 528 pp., \$19.50/£13.85 ISBN: 0-12-698750-5

REVOLUTION AT WORK

MOBILIZATION CAMPAIGNS IN CHINA

By CHARLES P. CELL

A Volume in the *STUDIES IN SOCIAL DISCONTINUITY Series*

This book presents the first quantitative research on China's mobilization campaigns. Using the best available data, it derives values for level of mobilization, achievements, and shortcomings of 36 selected campaigns. It uses these values to rate the utility for China's socialist transformation process of the three basic types of cam-

paings: economic, ideological, and struggle. Surprisingly, it finds economic campaigns (with the Great Leap Forward as one of the few exceptions) to be the most efficient, and struggle campaigns to be the least. It also provides historical and theoretical background on the campaigns, and discusses their future in the wake of Mao's death.

1977, 240 pp., \$14.95/£10.65 ISBN: 0-12-164750-1

POSTWAR FERTILITY TRENDS AND DIFFERENTIALS IN THE UNITED STATES

By RONALD R. RINDFUSS and JAMES A. SWEET

A Volume in the *STUDIES IN POPULATION Series*

This book examines trends and differentials in fertility within the United States since 1945. These trends and differentials are studied within social and economic subgroups, and within a period, rather than cohort, framework. The first general study of fertility to use extensively the Public Use Samples for the 1960 and 1970 censuses,

the book documents two major unexpected findings: The dominant fertility trends (the baby boom and subsequent decline) repeat themselves in virtually all social and economic subgroups; and yet social and economic differentials in cross-sectional fertility levels have persisted.

Tales Out of School *Implementing Organizational Change in the Elementary Grades*

Leila Sussmann

This participant-observer report highlights the problems of organizational change in three elementary schools: an integrated ghetto school, an ethnically mixed urban school, and a white middle-class suburban school. It is filled with insights into the validity and problems of instituting individualized instruction and open education. It also offers vivid accounts of school conditions such as resistance to change, unclear goals and external pressures that often block the implementation of changes that have been adopted.

290 pp. November ISBN 097-2 \$15.00

Society Under Siege

A Psychology of Northern Ireland

Rona M. Fields

From testing and interviews with the people of Northern Ireland, the author has developed a case study of the long-term effects of stress on a population. She identifies social control mechanisms which produce a mixture of chaos and docility and argues that England established these in order to destroy the identity of the people—a process she calls "psychological genocide."

Dept: _____

This report presents the results of a three year study which investigated the effects of New York State's strict drug law enacted in 1973. The analysis traces the impact of the law on narcotics use and drug-related crime. The process of implementing the law by the State's criminal justice system is also examined. This qualitative and quantitative analysis is one of the first of its kind undertaken to evaluate the results of a legislative program designed to combat crime. The report can be helpful to other states which are developing strategies to control illegal drug use and crime.

MASTERS OF SOCIOLOGICAL THOUGHT

Ideas in Historical and Social Context
Second Edition

LEWIS A. COSER, State University of
New York at Stony Brook

This classic history of sociological theory presents studies in depth of the outstanding sociological theorists from the early 19th century to the present. This Second Edition features three new chapters—Chapter 13 on Sorokin, Chapter 14 on Thomas and Znaniecki, and Chapter 15 on major American figures whose theories have come to the fore in recent decades.

611 pages

SOCIAL CHANGE IN THE TWENTIETH CENTURY

DANIEL CHIROT, University of Washington

In this lively and lucid introductory textbook, Daniel Chirot brings to the study of sociology a "world systems" approach. Drawing on extensive data from a wide range of fields, the author demonstrates the economic, political, and social interrelatedness of all nations and suggests how changes within—or among—societies results in social change worldwide.

Paperbound. 273 pages

DEATH AND SOCIETY

A Book of Readings and Sources

JAMES P. CARSE, New York University

ARLEEN P. DALLERY,

La Salle College, Pennsylvania

This collection of 35 provocative readings presents opposing viewpoints on six highly controversial aspects of death and dying: abortion, euthanasia, suicide, death and the law, death and aging, and death and the caring institutions. Numerous editorial aids assist students in weighing the social implications, as well as the merits, of each argument posed in the text.

Paperbound. 472 pages

THE LONGEST WAR

Sex Differences in Perspective

CAROL TAVRIS

CAROLE OFFIR, San Diego Mesa College

Under the Series Editorship of

IRVING L. JANIS, Yale University

This informative and entertaining volume offers a balanced and eclectic overview of differences between the sexes. The authors draw on major perspectives in the social, behavioral, and natural sciences to provide students with a rich and readable summary of sex differences and an appreciation of why those differences have evolved.

Concerning manuscripts, address: Editor, *American Sociological Review*, Dept. of Sociology, Uni-
versity of Illinois, Urbana, IL 61801.

Concerning advertising, changes of address, and subscriptions, address: Executive Office, American
Sociological Association, 1722 N Street, N.W., Washington, D.C. 20036.

The *American Sociological Review* is published at 49 Sheridan Avenue, Albany, New York, bi-
monthly in February, April, June, August, October, and December.

Applications for permission to quote from this journal should be addressed to the Executive Office.
Copyright © 1977 American Sociological Association.

ISSN 0003-1224

Annual membership dues of the Association: Member and International Member, \$30-50; Student Member, \$15; Associate, \$20; Student Associate, \$10; International Associate, \$12.

Application for membership and payment of dues should be made to the Executive Office.

Subscription rate for members, \$10; non-members, \$15; institutions and libraries, \$30; non-member students, \$10. Single issue, \$4.

New Subscriptions and Renewals will be entered on a calendar year basis only.

Change of Address: Six weeks advance notice to the Executive Office and old address as well as new are necessary for change of subscriber's address.

Claims for undelivered copies must be made within the month following the regular month of publication. The publishers will supply missing copies when losses have been sustained in transit and when the reserve stock will permit.

Second class postage paid at Washington, D.C. and additional mailing offices.

(Articles in the REVIEW are indexed in the *Social Sciences Index*, Public Affairs Information Service, Psychological Abstracts, Sociological Abstracts, Ayer's Guide, University Microfilms, Abstracts for Social Workers, United States Political Science Documents and International Political Science Abstracts.)

Beginning January, 1978 a processing fee of \$10 will be required for each paper submitted; such fees to be waived for student members of ASA. This reflects a new policy of the ASA Council and the Committee on Publications affecting all ASA journals. It is a reluctant response to the rapidly accelerating costs of manuscript reviewing. A check or money order, made payable to the American Sociological Association, should accompany each submission. This fee must be paid in order for the review process to begin.

ITEMS

December, 1977

This is my last issue. Rita Simon will become editor of the ASR with the February issue. I owe thanks to four groups of people who were crucial to the quality of the ASR in the last three years: first, to the deputy editors of the ASR, Barry Edmonston, Mike Hannan and Barbara Rosenblum. I am not sure how far back the institution of the deputy editor goes, but as the volume of manuscripts increases so

does the importance of the deputy editor to the quality of the ASR. It is the deputy editors who assign most of the manuscripts submitted to referees. Hence, they are as important as the editor to the final content of the *Review*. I am not sure that the authors and readers of the ASR have quite grasped how crucial the deputy editors are; but I have, and I am

PRESIDENTIAL ADDRESS: COUNTERCULTURES AND SOCIAL CHANGE*

J. MILTON YINGER

Oberlin College

American Sociological Review 1977, Vol. 42 (December):833-853

It was a rather simple issue which I decided to examine on this occasion: to design as parsimonious a theoretical statement as possible regarding a set of problems with which I have been concerned for many years. The set, as it turns out, has several parts:

Religious sectarianism and such related concepts as charisma, heresy, antinomianism, gnosticism and revitalization.

Anomie and alienation—the causes and effects of normative voids and individuals' experiences thereof.

Freudian and other depth psychologies, with their conceptions of a characterological underworld, filled with impulses and tendencies in sharp contradiction with the conscious life of the ego and the normative order of the superego.

Socialization and social control—particularly the forces that interfere with socialization and increase the intensity of social control.

Deviation, its sources and outcomes; the inverted values of some criminals and delinquents.

Youth groups and age groups generally; generation conflicts and their causes.

Gemeinschaft und Gesellschaft; the mass society; the return to community in communes; utopias.

Collective behavior and its relationship to customary behavior; the influence of mass media.

Political sociology; protest movements; revolutions; modernization and counter-modernization.

Social stratification, discrimination, prejudice; and the forms of protest against them made by dominated groups.

Rites of rebellion and rituals of reversal in tribal societies; saturnalia, feasts of fools, and "Abbeys of Misrule" in feudal and modern societies.

The sociology of knowledge, of literature, art, and music. And, of course, in such a melange, social change.

Indeed, it was a rather simple issue—simple enough for a good question on a doctoral exam: "Read the literature dealing with the following thirteen topics and then write a paper showing how that literature converges on a common set of problems." I've been giving myself that exam for thirty years and have written rather extensive answers to some segments of it. But none of the answers grapples with this complex of issues as a whole. What one needs is a unifying theme, a concept that will focus attention on the analytic problems common to the segments.

To serve that purpose, I am working with the concept of counterculture, which I will define here—postponing a fuller definition briefly—as a set of norms and values of a group that sharply contradict the dominant norms and values of the society of which that group is a part. My aim here is to examine a few of these topics to discover what they may contribute, when studied by use of the concept of counterculture, to our understanding of society. This is certainly a paradoxical way to approach problems of sociological theory. The central questions have always been: How can we account for social order? And how is change from one system

*I am deeply grateful to the National Endowment for the Humanities for a Fellowship for Independent Study and Research, to Oberlin College for a sabbatical leave, and to Clare Hall, Cambridge University for appointment as Visiting Fellow.

of order to another brought about? I am proposing that we approach these questions in a different way, that we look for explanations of disorder in the hope that we can increase our understanding of the basic problems of sociology by seeing them in a new light. This light will also cast its shadows, of course, and leave dark places; so it is best used in conjunction with, or in alternation with, other perspectives. It may be well, therefore, to glance at the basic questions in the more usual light before seeing them counterculturally.

Social theorists have developed, of course, three partially competing theories of social order:

It is a product of a mutually shared normative system—a blueprint for action that has been internalized by a set of persons in interaction.

It is a product of reciprocity and exchange, of perceived mutual advantages.

It is a consequence of the power of some to command the behavior of others—the reciprocal of power being the fear of sanctions, of loss or pain or death.

Statements such as these are best seen as analytic. A given interaction, a specific social situation is likely to be a product of all three factors, although one may predominate. Norms may be exploited for power purposes; exchange arrangements may get "frozen" into culture; power long exercised may take on the trappings of authority—a cultural concept.

Quarrels among theorists over the "true" or "basic" source of order seem pointless. The task is to measure the range of empirical mixtures of norms, power, and reciprocity and then to explore the conditions under which these mixtures occur. The mixtures undergo continual change, hence the study of social order must at the same time be a study of social change. Any one of the three sources of order—or more commonly some combination—may be involved in the process of change: Normative agreement may break down; power balances, or more precisely stable power imbalances, may shift; individuals and groups may gain or lose in what they have to offer in exchange. Under these conditions, ex-

pected satisfactions are unfulfilled and newly envisaged satisfactions are kept tantalizingly out of reach.

This is where countercultures come in. Some individuals and groups feel particularly strongly that the social order is unable to bring them the accustomed or the hoped-for satisfactions. Depending on their social location and on their personal tendencies, they attack, strongly or weakly, violently or symbolically, the frustrating social order—that is, the normative-power-reciprocity system. The nature of the attack varies widely, with some believing that they have been caught in very bad bargains, others that they are being exploited by unjust and unwise leaders or rulers, and still others emphasizing that they are surrounded by a shoddy system of norms and values. All three elements are found in most protest movements, even though they can be distinguished analytically. Giving the terms sharper and more limited meanings than they ordinarily carry, we can say that reform movements are efforts to change the social bargains—the exchange rates; rebellions are attempts to change the rulers and the bases of power; and countercultural movements are attempts drastically to reorganize the normative bases of order. Revolutions, which are rare and usually require several decades, include all three.

Our concern here is with normative systems in sharp opposition to the prevailing culture, and with the groups and individuals who are proponents and carriers of the oppositional culture.¹ Attention to social organization and social structure must be complemented, we have come to agree, by attention to the fact that conflict is

¹ It has become nearly standard to use the term "counterculture" to refer both to the norms and values and to the groups with which they are identified, after the fashion of most anthropological uses of "culture." This is not my preference. I think it blurs distinctions that are often essential to clarity. Yet I do not want to carry the burden of another neologism—countergroup or countersociety—to serve as a parallel concept. Therefore, I will use various circumlocutions to make the distinction between culture and society, between normative systems and the groups that carry them; and on occasion will refer to both by "counterculture" when I think the context prevents misunderstanding.

endemic, presenting a need for synthesis. Similarly, the emphasis on normative integration, on culture as a governing blueprint, must be modified by *continuous* attention to countercultures, while working toward synthesis. I am suggesting not simply a philosophical dialectic, based on the belief that every theoretical argument is self-generating, since every thesis contains the germs of its own contradiction, but a cultural dialectic: every normative system contains the seeds of its own contradiction. This is not propounded as a truth, of course, but as a point of departure, a fruitful way to begin the study of societies.

In each of the thirteen topics mentioned at the start, the cultural-countercultural dialectic has appeared; only by dealing with it will we be able to resolve pressing problems of analysis and interpretation. Ideological as well as evidential factors have tended to make it difficult to attain a perspective that continuously and simultaneously examines structure and change, culture and counterculture. That we must strive to do.

In the current emphasis on power and exchange, contemporary sociology is largely unaware of the deeply nonrational forces at work in all societies, forces that are built around symbol, ritual, and myth. Most of us are ready to recognize the unconscious and nonrational aspects of individual life, but pay too little attention to the counterpart on the societal level—the shared myths and rituals by which we collectively strive to avert crises or deal with them if they come. We can think of culture on its most abstract and mythical level as a paradigm that selects, interprets, and powerfully affects our impressions and feelings and desires. When culture begins to leave many questions unanswered and many needs unfilled, when individuals suspect their own emotions and experience only a blurred identity, the cultural system may be pushed aside (Tiryakian, 1974:1–15). Periods of cultural crisis (a potential at any time), of anomie, are not simply periods of loss of faith, but of struggle toward some new way to deal with the threat or reality of crisis and chaos.

THE DEFINITION OF COUNTERCULTURE

In the seventeen years since I proposed the term, several explicit and dozens of implicit definitions of counterculture have been offered.² We can begin to sketch out the parameters of the concept by examining some of these definitions.

There are fundamentally two ways of defining what a counterculture is, the first on an ideological level and the second on a behavioral level. On the ideological level, a counterculture is a set of beliefs and values which radically reject the dominant culture of a society and prescribe a sectarian alternative. On the behavioral level, a counterculture is a group of people who, because they accept such beliefs and values, behave in such radically nonconformist ways that they tend to drop out of the society. (Westhues, 1972:9–10)

The statement that countercultural groups tend to drop out of society is problematic, as Westhues recognizes. Some do; others stay engaged, hoping to change society and its values; others look inward, searching for their souls, but not leaving society.

Some definitions proceed mainly by illustration. Contrast minor variations on a cultural theme, Fred Davis suggests, with sharp variations.

The gang boy configuration . . . fits nicely Yinger's notion of a contraculture; its very meaning and existential quality inhere in its members' patterned deviation from the dominant American cultural pattern. . . . hippies, too, are an instance *par excellence* of a contraculture whose *raison d'être* . . . lies in its members' almost studied inversion of certain key middle class American values and practices. (F. Davis, 1971:4)

Davis then spells out these contradictions of value and practice in some detail:

immediacy contra past preoccupation and future concern; the *natural* . . . contra the

² I preferred and used the Latin prefix, hence contraculture. But the voice of the people has spoken, and the usual spelling, by about three to one, is now counterculture. To my ear, contraculture is more mellifluous. I also wanted to avoid suggesting a close parallel with counter-revolution and counter-reformation, with their rather specific connotations of returning to an earlier situation. Yet, like Mark Twain, I have no sympathy for those ignorant people who know only one way to spell a word.

artificial . . . ; the *colorful* and *baroque* contra the classical, contained, and symmetrical; the *direct* contra the mediated, interposed, or intervening . . . ; the *spontaneous* contra the structured; the *primitive* contra the sophisticated; the *mystical* contra the scientific; the *egalitarian* contra the hierarchical; the *polymorphous* and *androgynous* contra the singular; the *diffuse* contra the categorical; the *communal* contra the private. (F. Davis, 1971:14-5)

There is a tendency to stereotype both the dominant and the hippie standards in Davis' description, as in many discussions of countercultures, in order to draw the sharpest possible contrast; but he does capture the ideological tone of at least one variant of contemporary countercultures.

Some definitions proceed from an opposite perspective:

Today's pop counterculture, especially among the young, is an awesome mix of maximum mindlessness, minimum historical awareness, and a pathetic yearning for (to quote Chico Marx) strawberry shortcut. To hell with established religions, with science, with philosophy, with economics and politics, with the liberal arts—with anything that demands time and effort. Dig the rock beat, kink up your sex life, meditate, tack a photo of Squeaky Fromme on the wall. (Gardner, 1975:46)

Amid the abundance of such descriptions and definitions, pro and con, it is difficult to reestablish the concept of counterculture as a useful part of a scientific vocabulary. Too often we illustrate the truth of Walter Kaufman's appraisal that as it becomes increasingly difficult to keep up with events in a field of study, many people feel a need for "bargain words that cost little or no study and can be used in a great variety of contexts with an air of expertise" (quoted in Schacht, 1971:xlix).

Any analysis of countercultures faces this problem. Some use it as a word of opprobrium, an indication of incivility, depravity, heresy, or sedition. For others, counterculture means hope and salvation, a unique and perhaps final opportunity to get humankind off the road to destruction. Some devotees with whom I have talked are offended when I suggest that countercultures have occurred in many times and places. Their response is a "religious" ob-

jection to any doubt cast on the uniqueness of their experience. They are implicitly supported by the host of writers who, in recent years, have discussed "the" counterculture. Others are aware of the frequency with which countercultures have appeared, but not wanting to reduce the enthusiasm of current participants, play down the historical parallels and emphasize the uniqueness of contemporary oppositional movements.

Certainly every counterculture has unique elements that for some purposes are appropriately the focus of attention. However, I shall be climbing up the abstraction ladder—often, it may appear to you to dizzying heights—to see the similarities. The term counterculture is appropriately used "whenever the normative system of a group contains, as a primary element, a theme of conflict with the values of the total society, where personality variables are directly involved in the development and maintenance of the group's values, and wherever its norms can be understood only by reference to the relationship of the group to a surrounding dominant culture" (Yinger, 1960:629).

This definition leaves several questions unanswered: Should we speak of countercultures when second level or subterranean values of a society are raised by some segment of that society to a primary place? The apocalyptic visions, populism, and evangelical fervor of American student radicals, Matza (1961) notes, are part of the dominant tradition. When these "counterthemes" are carried to an extreme, however, they are "publicly denounced." Delinquent youth can also draw on a subterranean tradition of the dominant society. The search for a thrill, the use of "pull," and aggression are scarcely limited to delinquents; they are secondary values of the dominant society (Matza and Sykes, 1961). At some point, an exaggerated emphasis on a value becomes, a counter-value by virtue of the exaggeration. We are dealing with a variable, and only careful study can tell us at what point an exaggerated value becomes countercultural, as indicated by the consequences of its use.

How is deviant behavior distinguished

from countercultural behavior? The latter is only one form of deviation, nonconformist and not aberrant, in Merton's terms (Merton and Nisbet, 1966:ch. 15). It is also supported by the norms and values of a group. When counterculture is used to refer to deviation, whether or not it is nonconformist and group supported, we are prevented from distinguishing behaviors which, although sometimes similar on the surface, are different in causes and consequences.

Is not the whole concept of counterculture riddled with class and ethnic bias in pluralistic societies? There is a growing tendency to view urban societies as so diverse culturally that each segment is, at the most, countercultural to the other segments. Empirical study tends to support the view, however, that most youths as well as adults hold to the values of the larger society. From their study of Danish and American high schools, Kandel and Lesser (1972:168) conclude that "far from developing a contra-culture in opposition to that of adult society, the adolescents we have studied express the values of adult society." A recent report on Britain's Sixteen-Year-Olds (National Children's Bureau, 1976) found that most of a sample of 16,000 were thoroughly traditional. Studies by Yankelovich (1974) and Wattenberg (1974) show wider deviations, especially among college youth; but the total impression is one of quite close identification with the values of society.

The degree of cultural diversity is not an either-or question, however; and countercultural theory must deal with the range of social situations, from those where value coherence and agreement are high to those where the common core is small (see Williams, 1970:ch. 10). *To the degree that* the total society has a shared culture, there can be reciprocal countercultures. And each subsociety can also have countercultures. Punk rock is not just a blue-collar deviation from upper-class music: it also drastically contradicts the musical and other values of the working class from which it springs.

How counter must a statement or action be (assuming it to be expressive of some norm or value of a group) before we shall consider it countercultural? In the most

limiting sense, we might say it has to be specifically a *reversal* of the established value. Note the use of such terms as "polarity," "reversal," "inversion" in the definitions I have cited. Berger and Berger (1971:20) speak of "diametric opposition." Indeed, these ideas are central to the original concept of counterculture (Yinger, 1960).

We have no way of saying with certainty, however, that sharply oppositional statements and actions are 180 degrees different from prevailing values. We have only the beginnings of a sociometry of dominant values (as in the work of Rokeach, 1973; Yankelovich, 1974; Williams, 1970; McCready and Greeley, 1976), and of measurement and scaling of countercultures (Musgrove, 1974; Wuthnow, 1976b; Wieder and Zimmerman, 1974; Spates, 1976; Spates and Levin, 1972; Wattenberg, 1974; Starr, 1974).

VARIETIES OF COUNTERCULTURES

One might organize material for a study of countercultures in various ways. The contrasting values and norms could be examined institutionally, with the orthodox or dominant patterns of economics, politics, education, family, and religion set against those of oppositional groups (see Wuthnow, 1976b: ch. 1; Gerlach and Hine, 1973: ch. 15). Or we could build on an analysis of human behavior that has proved to be useful in several other fields. Years ago Karen Horney (1937) noted that neurotics tend to struggle with their anxieties in three different ways: by attack, by withdrawal, or by a search for shelter and protection. Charles S. Johnson (1943) skillfully described the ways in which minority-group members dealt with discrimination by aggression, avoidance, or acceptance. Turner and Kilian (1957) develop a highly analogous interpretation of power-oriented, value-oriented, and participation-oriented social movements. There is a further close parallel in Weber's (1963) description of prophetic, ascetic, and mystical sects.

I shall not develop this valuable theoretical convergence, more than to say that countercultural groups quite clearly fall

into the same threefold pattern, not the twofold activist-withdrawal categories ordinarily used. The closest comparison is with types of sects. The radical activist counterculturalist is the prophet who "preaches, creates, or demands *new* obligations," to use Weber's words. In typological terms, the communitarian utopian is the ascetic who withdraws into a separated community where the new values can be lived out with minimum hindrance from an evil society. Neither of these descriptions fits the mystics searching for the truth and for themselves. Realization of their values requires, in their view, that they turn inward. They do not so much attack society as disregard it, insofar as they can, and float above it in search of enlightenment. "The enemy is within each of us," says Charles Reich (1970:356-7).

Although every countercultural group tends to be a mixture, the strains and the splits they experience often result from sharply contrasting views of the best way to realize their oppositional values. When at the 1969 Woodstock festival, for example, Abbie Hoffman tried to generate political action by saying that the festival was meaningless until a radical "rotting in jail" was freed, a member of The Who rock band, in the words of *Rolling Stone*, "clubbed Hoffman off the stage with his guitar" (Denisoff and Levine, 1970), a wonderfully symbolic way to express the conflict. From the perspective of prophetic counterculturalists, the tendency of many participants in the "New Left" to define political problems in terms of personal issues, often in the language of alienation, seems a terrible deflection from the basic goal of achieving a society based on new values (Lasch, 1969; Clecak, 1973). In theory, if not always in their own ideologically guided behavior, they share Weber's (1946:126) view that "he who seeks the salvation of the soul, of his own and others, should not seek it along the avenue of politics."

A group may seek to mix the mystical-experiential and the ascetic-communal countercultural modes, until it is clear that the search for wisdom and the ultimate trip doesn't get the corn planted or the groceries bought, whereupon the group

breaks up, or some members leave for a setting more in keeping with their inclinations. In recent years, persons who had sought salvation through drugs and unrestrained sex have sometimes turned to ascetic and highly restrained religious groups—the Divine Light Mission or Hare Krishna or Meher Baba (Kelley, 1973; Judah, 1974; Zaretsky and Leone, 1974; Glock and Bellah, 1976; Robbins and Anthony, 1972).

Other than this brief reference, I will not follow the institutional or what can be called the sectarian way of organizing the discussion of oppositional cultural movements. We can develop more meaningful comparisons and more useful general principles by examining the following questions.

Are there drastic shifts in the criteria and the methods by which a group claims to *know* what is true, good and beautiful?

Are there drastic shifts in the standards of what are *held to be* true, good and beautiful?

In the traditional categories of philosophy, we can define countercultures in terms of their epistemologies, their ethics, and their aesthetics. The events we study will almost always combine various elements; but we can understand the blends better if we keep in mind the elements out of which they are built.

(1) Truth, today's counterculturalists declare, is not attained by arid research but by mystical insight. It is found in populist, homespun wisdom, in anti-universities, in direct experience with the cosmos, in meditation, in chants, in drugs, in sensory deprivation, in sensitivity to the messages of the intuitive right hemisphere of the brain—all this set over against science, technology, the knowledge of the expert, and cold rationality.

Attacks on the intellectual establishment are scarcely new, of course. The Taborites denounced the masters of Prague University in the fifteenth century. In England, during the period preceeding the Civil War, sectarians called for discussion after sermons (a practice adopted for a brief period in Boston). Itinerant interrupters, professionally skilled hecklers, moved among the churches, which were indissolubly linked with the universities,

and despite legal difficulties, denounced the self-righteousness of the pastors and their greed in taking tithes (Hill, 1975:105-6). Truth, they declared, was not the monopoly of the clergy, but could be given to anyone through an inner light. It would require little shifting of terms to use this set of activities and claims to describe a free university in London or Berkeley in the 1960s.

Many persons share the distress that underlies these views, a distress that led H. G. Wells to say at the end of World War II, that "mind is at the end of its tether." Today we see even more clearly that some of our deepest problems come from application of scientific findings. The countercultural epistemology appears in response to this predicament. Pursue a sense of mystery and fantasy, embrace the occult, meditate, unlock the truth that is in you (Brown, 1966; Roszak, 1973; A. Smith, 1976).

Belief in the occult and the pursuit of understanding through mystery are, of course, persistent elements in human history. But their strength alternates, with waves of mysticism occurring when a society has experienced, as Tiryakian has put it, "a loss of confidence in established symbols and cognitive models of reality. . . . Occult practices are appealing, among other reasons, because they are seemingly dramatic opposites of empirical practices of science and of the depersonalization of the industrial order" (Tiryakian, 1972: 510, 494; see also Gellner, 1974; Wuthnow, 1976a).

The way paved for the countercultural epistemology of our time by the long tradition of unmasking in European and American thought (along with other sources). Do not trust appearances or presumed objective truth, for there are deeper realities, say Hume, Marx, Nietzsche, Freud, Pareto, and many others. Truth requires that we bring these deeper realities to light (See Mannheim, 1936; Merton, 1968; Ellenberger, 1970). If this unmasking laid the groundwork for the sociology and psychology of knowledge in the thought of some persons, it supported the search for truth through mysticism and the occult among others for whom science itself has been unmasked.

(My statement itself, of course, is an hypothesis in the sociology of knowledge.)

(2) Countercultural ethics contradict the values of the dominant society as sharply as countercultural epistemology. Proponents of one, however, are often not proponents of the other. Those who oppose the established ways to truth may be quite conservative in their definitions of the good life; while those who condemn the morality of the establishment may be quite comfortable with its epistemology. The search for a "new head" has much more often been associated with quietism, introversion, and withdrawal from an evil world than with efforts to change it. These tendencies are not characteristic of those I call ethical counterculturalists. They challenge the world with new visions of the good life.

To the seventeenth-century English Ranters, the prevailing moral law was not binding on the true believers. "I know nothing unclean to me," Clarkson wrote, "and therefore what Act soever I do, is acted by that Majesty in me" (quoted in Cohn, 1970:312). Do your own thing is a somewhat less elegant way of putting it. Many Quakers and Ranters went naked through the streets and into churches—no segregated nudist beach for them (Cohn, 1970; Hill, 1975). Abiezer Coppe and his more effervescent followers were a free speech movement, using obscenity as a weapon; they affirmed the rightness of sex before marriage and attacked the monogamous family; they supported the use of drugs to heighten spiritual vision (though it was alcohol and the new drug tobacco); they dismissed the prevailing doctrines of the church and its structure of authority; they rejected private property in favor of communism.

The Ranter ethic, as preached by Coppe and Clarkson, involved a real subversion of existing society and its values. . . . all that matters is here and now. . . . Nothing is evil that does not harm our fellow men. . . . "Swearing i'th [giveth] light, gloriously," and "wanton kisses" may help to liberate us from the repressive ethic which our masters are trying to impose on us. (Hill, 1975:339)

To the contemporary counterculturalists, what feels good is good. This sometimes collides with another principle:

if it is good to the establishment, it is bad for us. Since the establishment takes a somewhat ambiguous middle position with regard, for example, to aggression and sex, countercultural groups have to push away from the center, toward pacifism and celibacy or toward violence and sexual exuberance, meanwhile claiming that the establishment is not in the center, but actually occupies the opposite pole from the one being held up as good. Counterculturalists do not escape the common human tendency to make their enemies, as well as their leaders, into what they need them to be—need them in an effort to justify their actions and handle their ambivalences.

(3) A culture is as fully defined by its aesthetic standards as by its epistemology and its ethics. In many ways the opposition of artists has been negative, in the sense that they have held societies and their cultures up to fundamental criticism more than they have affirmed the values of a counterculture. Yet some oppositional art by its very creation defines an aesthetic counterculture, by using forms and sounds and ideas that formerly were taboo. As culture rather than as criticism, the contemporary counterculture scarcely runs the gamut. Its range is more nearly from yoga to yogurt to zen. The appeal to chaos and dissonance and the overwhelming of the senses correspond with many experiences of our time; but when that point has been made, we may begin to demand of our artists that they help us find—help us experience—some new sense of order and consonance.

I have said, help us experience, because it is not art as argument, but art as experience that more strongly carries the countercultural (or the cultural) impact. "The world doesn't fear a new idea," D. H. Lawrence wrote. "It can pigeonhole any idea. But it can't pigeonhole a new experience" (quoted by Trilling, 1966:xvii). In a society whose major values are intact, the artistic experience, though filled with turmoil and agony, becomes, in the last analysis, an affirmation of those values. In a society torn by doubt, much of the art—often including some of the best—will take us into a different world. The

pilgrim in Dante's *Divine Comedy* moved from low to high, into a kind of rebirth. Samuel Beckett has his heroes, if that is the word, still *Waiting for Godot* as the curtain falls. The protagonist of Kafka's fable is no nearer *The Castle* at the end of his journey than at the beginning.

As experience, many novels and plays in the "theatre of the absurd," using that term in a broad sense, are countercultural comments on the world (see Esslin, 1973, for a more restricted usage). Even this absurdity that we dramatize, they say, makes sense by comparison with our sorry state. Let a brief comment on Jean Giraudoux's *The Madwoman of Chaillot* stand for a variety of plays and novels. To understand the world they affirm, we shall have to turn our usual perceptions upside down. With a wonderfully comic touch, Giraudoux holds the rich, the power hungry, the presumably successful up to ridicule. The industrialist, the general, the broker, the southern fundamentalist minister, and the commissar are seen as truly mad. They are about to destroy Paris and the world as they seek to get the oil they believe is under the city, while the "madwoman" with her eccentric friends recognize the absurdity in the powerful and try to stop them.

I shall only point to some of the other forms of aesthetic counterculture—those drastic efforts to redefine the beautiful, to break away from old standards that seem not only to inhibit the imagination but to confirm the whole culture within which they are embedded. Some of these innovations, by their artistic merit and the timeliness of their appearance, change the culture and become part of new aesthetic traditions, whether classical or popular. Other innovations fade rapidly, particularly if they are to an important degree a vehicle for carrying other kinds of protest than the aesthetic one.

Most great musicians push back the boundaries of the received tradition and are sometimes regarded as countercultural by defenders of the prevailing classicism. Though counterpoint has long been regarded simply as one aspect of harmony, when it first appeared in the late medieval period, with its polyphonic styles, its in-

dependent rhythms and distinctive sets of sounds, it was an affront to those who knew how music "should" sound. Even some of Bach's contrapuntal forms—turning a melody upside down or running it backward—seemed harsh to some of his contemporaries. But it was inevitable—if I can offer a sweeping and quite unsupported hypothesis in the sociology of music—that the growing complexity of society should be expressed in the growing complexity of music.

To leap into our own century, Schoenberg and Stravinsky and many others turned against the romantic tradition, as many of their literary contemporaries did, to explore the farthest possibilities of dissonance—one is tempted to say in a world filled with crashing sounds and disharmonies.

Seen against the history of music, it comes as no surprise that popular as well as classical forms can drastically challenge prevailing standards. The contemporary counterculture in music, to be sure, seems to bring a much more powerful dissent, both in the sharpness of its reversal of standards and the breadth of its influence. The enormous power of the electronic media to give voice to new sounds, the economic resources to produce them and listen to them, the depth of the disenchantment and its expression in so many other ways, all support the musical protest of our time. For some, of course, rock music is entertainment, fad, and declaration of independence; or it is a source of great profit (Eisen, 1969:xiii). For others, however, it is the chief ritual of a new life; it is community; it is religion. The whole culture complex—the music, lyrics, volume, artifacts, audience, set, and setting—facilitates, as Harmon (1972:81) puts it, "an unprecedented questioning of basic cultural values and institutions." The "acid rock" groups have given coverage and confirmation to the use of drugs; the lyrics define a new morality ("All the things they said were wrong are what I want to be"); the festivals bring together a community that supports the new values; the music itself declares that the old harmonic and well-modulated sounds of the past are the sounds of a repressive society.

CANDIDATES FOR COUNTERCULTURES

Countercultures can best be identified, I have suggested, by studying movements based on epistemological, ethical and aesthetic standards sharply at odds with prevailing norms. Why are some people drawn to the new standards while others are repelled by them? A theory of countercultures must connect oppositional normative movements with individual personalities. Freud saw us all as good candidates for behavior that contravenes the norms because, as he put it, "what we call our civilization is largely responsible for our misery" (Freud, 1962:33) by blocking strongly motivated activities. Freud stated a principle that today we call hedonic relativism, a term similar to relative deprivation: "We are so made," he wrote, "that we can derive intense enjoyment only from a contrast and very little from a state of things. Thus our possibilities of happiness are already restricted by our constitution. Unhappiness is much less difficult to experience" (Freud, 1962:23-4). Although he does not locate the cause in the individual psyche, Durkheim had earlier made a similar point. One can only be disillusioned, he remarked, if one moves toward a point that "recedes in the same measure that one advances. . . . This is why historical periods like ours, which have known the malady of infinite aspiration, are necessarily touched with pessimism" (Durkheim, 1973:40).

We all know, from experience and experiment, how readily we accommodate to new standards of enjoyment, so that what seemed pleasant yesterday is now unacceptably bland. "Where pleasure is concerned, humans are insatiable animals, shifting their criterion level upward when the level of pleasurable input increases, so that once again experience is scored as one-third pleasure, one-third pain, and one-third blah" (Campbell, 1975:1121). We do not make equally quick adaptation to any downward pull of experience. There is nothing more painful, as Veblen noted, than a retreat from a standard of living.

Granted this principle, a society that enormously raises the aspirations but only

modestly raises the pleasures of its members, or some of its members, is furnishing an essential ingredient of protest. Even if there are gains in some objective sense, many will feel cheated by society and disenchanted with its values. These are perhaps the conditions under which a shift occurs, in Ralph Turner's (1976) terms, from institutional definitions of "the real self" toward impulse definitions. What he calls impulse selves also require social validation and support from others. What start out as impulse selves may be collectively validated as the partially institutionalized selves of a counterculture.

The criteria by which Turner defines the impulse self are similar to those used by Keniston and others to describe alienation (Keniston, 1965; Bloy, 1969). Living for today, rejection of "success," emphasis on "being" rather than on "doing," self-expression and the lowering of inhibitions are tendencies that Keniston (1965:81) sees as point-by-point denials of the established values and replacement by their opposites.

In addition to impulse self and alienated self, other terms can be used to help us examine the individual counterpart of countercultures. Adler (1972) discusses the antinomian personality, and Erik Erikson, using perhaps the most useful psychological analogue for counterculture, develops the term "negative identity." In an often desperate choice between being a failure, a nobody, an "invisible man," and being a shockingly visible anti-hero, a person to reckon with, some choose the latter, expressing their frustration "in a scornful and snobbish hostility toward the roles offered as proper and desirable in one's family or immediate community." It is not simply that standard roles are abrogated. "They choose instead a *negative identity*, i.e., an identity perversely based on all those identifications and roles which, at critical stages of development, had been presented to them as most undesirable or dangerous and yet also as most real" (Erikson, 1968:172-4).

Erikson tends to assume that a negative identity is pathological. It may be wiser to reserve one's judgment on that issue, asking in each instance what a person is being

negative against, what balance of creativity and inanity is found in the available positive identities, and what the consequences are for the individual and society in the various choices. Such self-feelings may be part of the character not only of the neurotic, but also of the prophet or the highly creative person who finds the preferred identities too closely bound to an unacceptable society. It is not only that individuals may be alienated, societies may be alienating. One psychiatrist, "when asked what he thought the best therapy was for students who had been severely alienated by the Vietnam war, replied, 'Stop the damn war!'" (Bloy, 1969:651).

Those driven to define themselves in terms that quite reverse the standards of their time and place are often torn by ambivalence (on ambivalence, see Merton and Barber, 1963; Room, 1976). Redl and Wineman note that although some delinquents so identify with criminal activity that they have few problems with guilt, "others are not quite that advanced. They still have mighty chunks of their value-identified superego intact. . . . In that case, the 'delinquent ego' has the additional task of 'duping its own superego,' so that delinquent impulsivity can be enjoyed tax-free from feelings of guilt." (Redl and Wineman, 1951:144).

Perhaps the counterpart of this is the need a participant in the dominant society—one who is also ambivalent about dominant values—has for duping his own id. The "long-haired, ne'er-do-well pot smokers" are the hidden and repressed parts of his own life—the dreams and fantasies of freedom from routine, inhibition, and the demands of work. By making advocates of such freedoms seem abhorrent, one can more easily resist temptation.

This interpretation ought not to be pushed too far in either direction, however. Genuine value conflicts exist; and the opponents are those who hold contrary values, not the hidden selves.

Because of their ambivalence, counterculturalists need opposition. In recent years, they have needed a "police state" and have helped to intensify already-existing tendencies in that direction

(Douglas, 1970:179). Harsh opposition helps to justify their feelings and actions and helps to push them away from the center, win attention, sympathy and converts, and draw sharper, value-protecting boundaries.

Although persons with feelings of negative identity are symptoms of and sources of countercultures, it is necessary to distinguish the individual from the group level. Not all those with negative identities support countercultural values or groups; not all who support countercultures have negative identities. Under some conditions, however, persons struggling with problems of identity and leaning toward a negative formulation are drawn into a social movement that validates their self-definitions and thus aids in the repression of the doubt and guilt that characterize ambivalent feelings. Or, in the absence of a countercultural group that gives validity to their negative identities, individuals may make tentative and ambiguous gestures to each other suggesting counter values, but leaving room for retreat or modification if the exploratory gestures don't lead toward consensus on the oppositional values (Albert Cohen, 1955:59-65; Klapp, 1969).

Even when the influence of social factors is taken into account, we should note that the concept of identity is not without problems. It has become loaded with implications and connotations related to the uncertainties of our time, as Bennett Berger (1971:90) says: "who would be so fatuous as to announce that he has found his identity." It is not even clear, in Berger's judgment, that finding it is a good idea. "A person who does not know who he is might *just be anybody*, and hence is fit for the unanticipatable opportunities and eventualities which rapidly changing industrial societies provide" (Berger, 1971:97). Having long thought that a dose of alienation and a dash of anomie were not only inevitable but essential in the modern world (Yinger, 1965), I share Berger's view to some degree. We are a long ways from knowing, however, what the long-run consequences of identity diffusion and of various levels of alienation and anomie are. Whatever the case, what requires study is the interaction between

given individual tendencies and countercultures, treating them alternately as the independent and dependent variables (see Kaplan, 1975; 1976).

RITUALS OF OPPOSITION AS COUNTERCULTURES

If countercultures are a continuing part of human experience, rooted in characterological and social constants, one should find them, in one form or another, in all societies. Their strength can be expected to vary widely, along with their specific or precipitating causes, but they should be found everywhere, in incipient or highly developed form.

This argument is put to its most severe test in its application to small, tribal societies, relatively isolated from contact with other societies. Many authors have described the role reversals and the rituals of rebellion and opposition that are not only permitted but sometimes required of persons occupying certain positions. Related to them are the saturnalia, the feasts of fools, the charivaris that come down to us from, at least, the days of classic Greece and Rome.

From James G. Fraser's *The Golden Bough*, to Gennep's *Rites of Passage*, to the work of Max Gluckman, Victor Turner, Jack Goody, Edward Norbeck, Peter Rigby, T. O. Beidelman, and many others, we have had a steady flow of ethnographic description and a variety of interpretations of rituals of opposition and of role reversals. Many American Indian tribes had burlesque ceremonies during which clowns "parodied serious rituals, introduced obscenity into sacred places . . . , and showed open disrespect for the gods themselves" (Wallace, 1966:136). A striking feature of the organization of the Zulu "is the way in which they openly express social tensions: women have to assert license and dominance as against their formal subordination to men, princes have to behave as if they covet the throne, and subjects openly state their resentment of authority" (Gluckman, 1963:112).

Such activities can be matched in the medieval and contemporary worlds. By the late fifteenth century, All Fools Days were banned by the cathedrals, but they

were picked up by laymen, by families, craft guilds or "sociétés joyeuses" who planned ribald festivals, Abbeys of Misrule. Lyon had a Judge of Misrule and a Bench of Bad Advice; Rouen's Abbot had serving him the Prince of Improvidence, the Cardinal of Bad Measure, Bishop Flatpurse, Duke Kickass, and the Grand Patriarch of Syphilitics (N. Davis, 1971:41-4).

Needless to say we have Halloween, football weekends, Mardi Gras, New Year's Eve, and twenty-four-hour rock concerts, all tolerated and to some degree protected by the agents of the official culture. Less obviously, but perhaps more powerfully, some teaching, particularly in the humanities and the social sciences, can be seen as a ritual of opposition attacking the established order and describing, or implying, an alternative cultural world.³

To some degree, to analyze a society is to weaken the mythic hold of its culture. I do not argue against this—indeed, at this moment I am engaged in such analysis—because the alternative, a kind of rigid ignorance, is more risky. Yet we need continually to remind ourselves that "a little learning is a dangerous thing." In a brilliant essay "On the Teaching of Modern Literature," Lionel Trilling (1966:3-30) observed that most of the best of modern literature is subversive, filled with "strange and terrible . . . ambivalence toward the life of civilization." From Blake and Wordsworth to Nietzsche, Conrad, Lawrence, Gide, Yeats, and Joyce (make out your own list) there runs a "bitter line of hostility" toward the dominant culture. By the time students have read Nietzsche's *The Birth of Tragedy*, Conrad's *Heart of Darkness*, and Dostoevsky's *Notes from Underground*, they seemed ready, as Trilling (1966:25) put it, to engage in "socialization of the antisocial, or the acculturation of the anti-cultural, or the legitimization of the subversive."

³ Particular circumstances, make a given discipline "a fulcrum for the rejection of established social arrangements" (Ladd and Lipset, 1975:73). During earlier periods, the physical sciences were also a source of radical challenge.

Such study—and the exams on the material—are a kind of ritual of rebellion, allowing strongly countercultural feelings and ideas to be expressed, but within a culturally permitted and ritualized frame of reference—the classroom—where participants see themselves and are seen as in a liminal phase, to use Gennep's (1960) term, surrounded by cultural ambiguities as they move from one social position to another.

How can we account for these sanctioned, even sponsored, deviations from the established cultures, these culturally circumscribed countercultures? They are most commonly seen as cultural inventions that serve, whatever their origins, as lightning rods. Gluckman (1954) described rituals of rebellion that blatantly subverted the usual moral and sexual norms as cathartic release mechanisms that lowered anger and resentment. It seems paradoxical, Wallace notes, that some people should be permitted, even required, to do the "wrong" thing, the culturally forbidden. "The paradox, however, is only a seeming one, for the ultimate goal is still the same: the maintenance of order and stability in society" (Wallace, 1966:135). Gluckman (1963) developed the distinction, formulated earlier by Aristotle (or, if you prefer, by Weber) between rebellion and revolution, and argued that only rebellion against rulers, not revolution against the system, could develop in tribal societies because they could envisage no alternatives. Such rebellions, he argued, were culturally contained and ritualized even as they permitted drastic counter-normative behavior.

These explanations seem to me to be, at best, incomplete. Even in the most isolated societies, persons who feel abused can imagine alternative norms and values in the form of contrast conceptions to those that prevail. Rites of opposition express a contradiction in society. They do not resolve that contradiction, but give voice to strongly ambivalent feelings. They often contain sharp criticisms of the social order, allowing some persons to express values that stand as potential reversals of the dominant values. This keeps such values alive while not compelling the participants to see themselves wholly in

terms of them. Such rituals also allow the orthodox, the "straights" to see and hear and sense the force behind alternative ways, perhaps breaking their cultural isolation and rigidity. As Victor Turner puts it, describing the contemporary "rock" experience: "The structure-dissolving quality of liminality is clearly present . . ." (V. Turner, 1974:263). He then goes on to note that the "rock" experience is ancient, arguing against those who suppose that contemporary rock music, with its accompanying group experiences and multiple stimuli, is unique. "Anthropologists the world over have participated in tribal 'scenes' not dissimilar to the rock 'scene' . . . 'synaesthesia,' the union of visual, auditory, tactile, spatial, visceral, and other modes of perception . . ., is found in tribal ritual and in the services of many modern religious movements. Arthur Rimbaud, one of the folk heroes of the counterculture, would have approved of this as '*un dérèglement ordonné de tous les sens*,' 'a systematic derangement of the senses' " (V. Turner, 1974:264). As a writer for the *Oracle* put it: "imagine *tasting* G-minor."

Of course we lack the kind of controlled study that would allow us to speak with confidence about the countercultural aspects of rituals of rebellion or more contemporary forms of sanctioned deviation. What we do have is the experience of seeing such rituals being developed before our eyes, in the form, for example, of rock festivals licensed by city officials and aided by the police—even as many of the norms and values of the dominant society are disregarded. By careful study over time we may be able to determine to what degree such rites promote cultural integration (or rigidity) by serving as safety valves and the degree to which they promote cultural change and conflict, by keeping alternatives alive.

SOCIAL CHANGE AND COUNTERCULTURES

Countercultures are variously regarded as engines of social change, symbols of change, or mere faddist epiphenomena. There are several ways to examine this disagreement.

Countercultures as Mutations

One way to study the connection between social change and oppositional movements is to glance at genetic mutations, which stand as powerful analogies to countercultures. If we take them as suggestive hints about similar processes that occur on the cultural level, study of these analogies can help us to describe, if not to explain countercultures.

Biological systems are self-reproducing, but they are not closed systems. In addition to natural genetic variations, they experience drastic discontinuities. Most mutations are maladaptive, and individuals whose genes are thus modified are less likely to survive or reproduce than more standard members of the species so long as the environment remains relatively stable. If there are significant changes in the environment, however, deviant individuals—those carrying the mutant gene—may have a survival advantage. Recessive genes can be thought of as a kind of gene bank where maladaptive mutations are sometimes stored, a survival resource to be drawn upon if drastic changes of environment make them adaptive (Gerlach and Hine, 1973:224–5).

Some cultural deviations can be seen as the mutations of a society's normative system. Since it is difficult to believe, however, that the individual-societal-environmental system is as well-balanced as the organism-environment system—the result of a process of evolutionary selectivity—we ought not to assume that most cultural deviation, like most mutation, is maladaptive. Nor should we assume the opposite, after the fashion of those who believe that any kind of change is preferable to stability. Some cultural deviations, like most mutations, are lethal.

Most social scientists today believe that rigidity is a greater threat than are cultural mutations. As Donald Campbell (1975:1121) has argued, in an important paper, social scientists and psychologists may be overeager "to discover and believe antitraditional, antirepressive theories"; they may be especially receptive to "the prophetic message of liberation."

The old ways, of course, may contain social adaptations that have become destructive under new sets of circumstances. Pressure against the traditional cultures, however, comes not only from their failures to adapt to new circumstances, but also from the hedonic individualism and self-centeredness that are the product of biological selection. The continuing task, Campbell argues, is to arrive at a minimax solution or a stable compromise between the needs and requirements of the biological and the social systems (see also Meddin, 1976).

Social norms the world over seek to limit selfishness, greed, and dishonesty, even though it can be argued that biological evolution favors individuals who practice them. "Look out for your own interests" may be as important as "thou shall not covet," Campbell observes, but spontaneous compliance with the former generally makes normative reinforcement unnecessary.

This is a powerful argument, but I would emphasize somewhat more than Campbell does the rigidity built into social systems, partly as a result, ironically, of the social virtues that make social life possible. He notes that in Moses' day, as in ours, honoring one's parents could have been carried to dysfunctional lengths, "but such excesses were so little of a social problem that 'Thou shalt show independence from thy parents' was usually omitted from the limited list of reiterated commandments" (Campbell, 1975:1118); usually omitted, perhaps, but not always. Several centuries after Moses, a charismatic prophet with countercultural tendencies declared: "For I have come to set a man against his father, and daughter against her mother, and a daughter-in-law against her mother-in-law; and a man's foes shall be those of his own household (*Matthew* 10:35, 36).

This quotation prompts me to suggest that major countercultural mutations often—I am tempted to say in the majority of cases—appear as religious movements. "The sect," says Werner Stark (1967:129) "is typically a contraculture." A set of values that changes life drastically, that threatens not simply opposition but persecution, that is entangled with deeply am-

bivalent feelings about one's self and others, demands a powerful revelation to a charismatic leader or a deep-going mystical experience or the support of a select community of believers if they are to be experienced as a viable new way of life. Charisma can be counterposed, not only to the sense of an excessive rationalization of life, but also to the sense that an established moral order must be broken (Weber, 1963; Roth, 1975). (Under some circumstances, of course, the charismatic leader seeks to protect and repair an endangered moral order [see Wilson, 1975].)

The religious element in oppositional movements is well expressed in Wallace's concept of revitalization—a term that overlaps the meaning of counterculture in many ways. "It can be argued," Wallace (1956:268) writes, "that all organized religions are relics of old revitalization movements, surviving in routinized form in stabilized cultures, and that religious phenomena *per se* originated . . . in the revitalization process—i.e., in visions of a new way of life by individuals under extreme stress."

To say that many cultural mutations are religious is not to say that they are good—or that they are bad. Most persons would probably agree that certain prophetic movements with which they identify have been major forces in transforming an unjust or otherwise inadequate social order. Not many are inspired with awe, however, by hearing from the Church of Satan that greed, pride, envy, anger, gluttony, lust, and sloth are cardinal virtues, not the seven deadly sins (Moody, 1974; Alfred, 1976). In noting that many countercultures are religious, I want simply to emphasize that those involved connect them with the fundamental problems of existence.

Countercultures as the Result of Social Change

Major countercultural movements are, in the first instance, indicators of a society experiencing severe stress. The common tendency today to associate countercultures only with the middle and upper classes fails to see that they are often a

two-pronged attack on the established culture, expressing different kinds of stress. On one side we get the countercultures of the privileged who say, in effect: here are values we can respect, that give us a sense of meaning. On the other side are the countercultures of the deprived who say: here are values we can attain, that give us a sense of control. To cite a diverse list of the latter, without explication, there are countercultural elements in "the culture of poverty"; among the Black Muslims, particularly in their earlier period; and in the values of delinquent gangs.

Thinking of countercultures as the dependent variable, we see many kinds of social change that upset the moving equilibrium of a social order, the structural-cultural-characterological balance of a given time, and make the appearance of countercultural movements more likely (none of these is a sufficient cause; some may be necessary; all are interdependent):

(1) Drastic reorganization of the way people make their livings. These ways are closely bound up with shared values and norms, with the power distribution, and with accustomed reciprocities. Rapid economic growth and related political changes, whether in industrialized or developing societies are closely connected with occupational changes and magnify their destabilizing impact.

(2) Changes in the size, location, age distribution, and sex ratio of a population. Insofar as a low average age is a factor, the most highly industrialized societies can expect a reduction of countercultural inventiveness, for better or worse. The average age in the United States is now 29—up from 25 a decade ago—and may be nearly 35 by the end of the century if present trends continue. The graying of America may prove to be a more accurate prediction than the "greening of America."

(3) Rapid importation of new ideas, techniques, goods, and values from alien societies or from earlier periods. By itself, this explains little, since one needs to know why the new ideas or goods seemed attractive, rather than repugnant, why cultural tariff barriers didn't keep them out. It is clear, nevertheless, that countercultural movements often use

foreign norms and values for their contrast conceptions; and the production and use of goods from another culture can, under some conditions, have a powerful dissolving effect on the established ways of doing things.

(4) Sharp increase in life's possibilities, hopes, dreams, and actualities, followed by a plateau, actual loss, or serious threat of loss. This has long been recognized as a factor in revolutions. Countercultural movements do not typically occur when desired values are becoming more difficult to attain, despite the ideology of the protesters, but when they have become more accessible over a period of time, although at a rate slower than the increase in demand. The result is a stronger sense of relative deprivation.

(5) Lower participation in intimate and supporting social circles—families, neighborhoods, work groups (Hendin, 1975; Berger and Berger, 1971). Many counterculturalists ranging from the utterly deprived to the "poor little rich kids," share in common a broken bond between parents and children that predisposes the latter to many forms of negativism. Some turn the negative impulses inward, which in our time has meant a sharp increase in rates of anxiety and suicide, or they may find support for turning the hostility outward. Feuer (1969) speaks of the deauthorization of the older generation as the major cause of the coalescing of individual oedipal problems into a shared revolt. He is one-sided in his interpretations and imprecise in his discussion of the sources of such deauthorization, though it seems reasonable to note its interdependence with the other sources of countercultures we have noted. The loss of intimacy between generations does not seem to have been overcome by the "love" generation, whose children are usually neglected in the name of permissiveness, much as they themselves were neglected (Yablonsky, 1968:302–15; Rothchild and Wolf, 1976).

(6) An increase in the number of antinomian persons, or those with negative identities, or in the strength of tendencies in those directions.

(7) A loss of meaning in the deepest symbols and rituals of society; or, if you

will, a religious crisis (Wuthnow, 1976b). The other factors we have mentioned doubtless contribute to the loss of meaning and several are, in turn, strengthened by it; but we are far from knowing why a major reduction in the legitimacy of the values of a society—rather than endemic but scattered skepticism—occurs. In a recent study of over a thousand university students in six countries (Yinger, 1977), I found that sixty percent believed that problems of meaning were the most fundamental issues facing humanity. (About half of these also mentioned problems of injustice, suffering, or both.) The present crisis of meaning is now generations old, and many feel, with Matthew Arnold (1907:321) that they are

Wandering between two worlds, one dead,
The other powerless to be born. . . .

Many of those caught in such a situation grasp for faith; they invent what they can (glorious religions are seldom the outcome) and they borrow meaning systems that seem uncorrupted by the society around them.

We need a theme? then let that be our theme:
that we, poor grovellers between faith and
doubt,
the sun and north star lost, and compass out,
the heart's weak engine all but stopped, the
time
timeless in this chaos of our wills—
that we must ask a theme, something to
think,
something to say, between dawn and dark,
something to hold to, something to love.
(Aiken, 1936:2)

We are moved by the poet more than by prosaic facts, but I think we need to guard against pluralistic ignorance—a shared belief in pseudo facts. It may be that a moderate reduction in the sense of shared fundamental values is so threatening that we are drawn to those sensitive voices warning of imminent danger.

(8) Such social and personality factors as we have mentioned create the context in which countercultures are likely to occur, but at least one other element is needed: communication among those with predispositions and living in situations that can precipitate countercultural values. Potential members need to identify one another; leaders need audiences;

powerful signals to and from the dominant society are required to help give protesters a sense of identity and to set boundaries. It is not by accident that the Diggers, Ranters, and Seekers, not to mention the more moderate Levellers, spread rapidly across England at a time when small printing presses were appearing in large numbers, when literacy was growing, and when the Puritans and the Royalists, struggling with one another, were for a brief period relatively tolerant of radical notions, each hoping to win support. It is scarcely necessary to note how much the TV camera, the mass circulation magazines and newspapers, the movies, as well as the enormously variegated underground press have spread the word in the contemporary Western world. More generally, the recurring conditions for countercultures are reenforced by direct lines of communication to the past and by the rediscovery and reemphasis of past leaders and movements (see Hill, 1975:ch. 18).

Countercultures as the Source of Social Change

When we turn the question around to ask how and to what degree countercultures are the cause of social change, we come to some of the most critical problems of sociological theory. With respect to recent American countercultures, a basically functionalist interpretation is now commonly given. Chief Justice Warren Burger of the United States Supreme Court recently declared "that turbulent American youth, whose disorderly acts he once 'resented,' actually had pointed the way to higher spiritual values" (*Cleveland Plain Dealer*, May 29, 1976:5-A). Philip Slater writes that a basic characteristic of successful social systems is the presence of devices that keep alive alternatives antithetical to the dominant emphases.

These latent alternatives usually persist in some encapsulated and imprisoned form ("break glass in case of fire"), such as myths, festivals, or specialized roles. . . . Such latent alternatives are priceless treasures and must be carefully guarded against loss. For a new cultural pattern does not emerge out of nothing—the seed must already be there. (Slater, 1971:110-1)

Well, some of them are priceless treasures and others are lethal bombs; but we may not be able to have one without the other. Slater's argument is close to Durkheim's interpretation of crime, which Durkheim declared; is necessary to the evolution of morality and law. "In order that the originality of the idealist whose dreams transcend his century may find expression, it is necessary that the originality of the criminal, who is below the level of his time, shall also be possible. One does not occur without the other" (Durkheim, 1938:70-1). And, of course, Durkheim goes on to say that crime not only implies that new ways are open; it may even be an anticipation of new collective sentiments. Socrates was a criminal, but he helped pave the way for a new morality.

I am uncomfortable with such unqualified functionalist views. Countercultures may stimulate the growth of highly resistant antibodies in society that make wise and necessary changes less likely. Opposition to the bizarre may deflect attention from basic needs; it may furnish those most resistant to change with superficially strong moral arguments, not to mention allies.

Antithetical groups do not escape each other's influence. We take on the face of the adversary, as the French proverb puts it, whether we wish to or not. Or, more technically, culture and counterculture are bound together in linked evolution. Under conditions of lowered legitimacy and loss of faith, efforts on the part of the dominant society to repress new norms and values can lead to deviation-amplification, not to a reaffirmation of the established norms and values. Efforts to coopt the deviants can, by legitimating their more moderate practices, have the same effect. Thus we need to complement Durkheim's view of the way deviation strengthens a group by an evolutionary view of the way it modifies a group. "If you're not part of the solution, you're part of the problem" is one of today's slogans. Gerlach and Hine (1973:260) offer us a similar notion: "if you're not part of a mutation, you are part of the environment which selects for or against it. No one can escape an evolutionary role." Deviant

ideas that become the operative values of a group tell us, at the least, something about the stresses faced by the members of that group. On another level, they can tell us something about the larger system, indicating points of inadequacy. On still another level, they can prove to be new values required to meet a new situation.

The changes in values and norms prodded by countercultures cannot proceed far without concomitant changes in social structure and character. Social change, as I use that term, is the process of movement from one relatively stable structural-cultural-characterological system toward another. This does not imply "that societies move from situations of relative balance, through periods of disruption, into new situations of balance. New forces may enter a system at such a rate that the realignment process cannot proceed rapidly enough" (Yinger, 1970:477). A situation where structural, cultural, and characterological elements are continuously out of phase with each other may now be endemic. It should not be assumed to be either exceptional or pathological. Nor should we assume that change must begin with one part of the system, with structural change in the economy, for example, or with the revelations of a charismatic leader, or with a shared cultural vision of what the new world should be. Whichever part of the social change process occurs first, its impact will be strongly influenced by the extent and direction of changes in the other parts.

Most revolutions show that structural change is more likely to be carried through than cultural change. In the early stages, revolutions usually contain a counterculture, carried along by a utopian conception of a new world. But those whose first concern is the transfer of power may believe this objective is threatened by demands for a new culture (Abner Cohen, 1974:ch. 3). After the transfer of power—often carried out in the name of new values—the new rulers don't seem very different from the old. From czar to commissar is not so far. Radicals fight the revolution; conservatives write the constitution. The family is attacked, to break the linkage of generations, but usually re-

turns to a pattern quite similar to its pre-revolutionary form.

The indirect effects of countercultures are probably more important than the direct and intended effects. The protest movements of mid-seventeenth-century England created a dissenting *tradition* that has outlasted some of the content of particular dissenting movements. This tradition has strongly influenced English and American history ever since. France and Germany, on the other hand, with much less strong traditions of dissent, have been more subject to revolutionary-counterrevolutionary cycles (see Baltzell, 1972:217-8).

Insofar as some upper-middle-class Wasps and Jews persist in their opposition to and withdrawal from technological society, Berger and Berger (1971) observe, they are less likely to modify that society drastically than to create new room at the top for the sons and daughters of manual workers—"The blueing of America." "If Yale should be hopelessly greened," the Bergers write, "Wall Street will get used to recruits from Fordham or Wichita State. Italians will have no difficulty running the RAND Corporation, Baptists, the space program" (Berger and Berger, 1971:23).

The effects of a given form of counterculture depend not only on its own characteristics, but on the situation. Suppose that it becomes essential for the United States to shift into a lower consumption, lower resource-using style of life. In the last few years we have discovered, once again, that even a small drop in accustomed levels of living exposes the society to enormous strains. All the political compromises and hard bargains through which a given distribution of resources has been attained are exposed. Without unusual support, lower consumption *values* would come about only from the effects of the slow and painful erosion of necessity. Now into this scene may come, not as a purposive invention but as a cultural mutant, a movement that reduces certain pleasure demands in the name of a powerful ideology that satisfies other needs. The reduction in what was formerly thought to be a high standard of living is not defeat; it is, in fact, the good life. We find "relig-

ious" support for the shift rather than sullen and strife-ridden retreat. Communes, ascetically inclined sects, hippies may help to devalue the pleasure currency, helping those involved and the many others pushed toward the new values by their appraisals of the situation, to balance their psychic economies. Without such shifts, we would have to think in terms of a continuously escalating pleasure-demand standard. The new values, of course, have a cost: painfully won disciplines, essential to other values, may be weakened; additional value shifts are tied into the change by the counterculturalists.

CONCLUSION

Someone has said that every country gets the socialist party it deserves. It is equally true that every society gets the countercultures it deserves, for they do not simply contradict, they also express the situation from which they emerge—pushing away from it, deploring its contradictions, caricaturing its weaknesses, and drawing on its neglected and underground traditions. If we shudder at the illegal drug problem, we ought more carefully to study our rates of alcoholism and lung cancer and the results of the use of other legal mind-altering drugs. If we shudder at the Manson family or the Symbionese Liberation Army, we ought to do more than contemplate the violence we do to some of our children in the ghetto or to the Vietnamese. If we shudder at the Church of Satan, we should at the same time note the aberrant violations of basic values by "respectable" people, violations that such nonconformist cults have transposed into virtues.

Lest I seem to be confirming only the negative image of countercultures, let me add: If we applaud the emphasis on gentleness and love, on conservation and sharing, on self-reliance and self-discovery that characterizes many oppositional movements today, we should recognize that these too—although expressed in the context of drastic value reversals—borrow from the dominant culture even as they oppose it.

The most important lesson from the

study of countercultures is not what it tells us about our times—or any specific time—but what it tells us about the human condition. In some ways, such a study underlines the points made by conservatives: the social fabric is delicate, it is based on long experience, it is built on constant factors in human life. Therefore, don't touch. This is often the wrong conclusion, however. Because the social fabric is delicate, we need continually to weave in new threads. A cultural-countercultural confrontation, a consequence of changing conditions and inflexible structures, is a costly way to proceed. We need to learn how to respond to early warning signals rather than waiting for over-compensating attacks powered by ambivalence and anger.

In my judgment, we are in the midst of a major civilizational transformation. The critical issue that humankind faces today is: How to create a rolling adjustment to the incredibly rapid and drastic changes taking place on the planet. We're faced with the problem of rebuilding the station, relaying and changing the gauge of the tracks, and accommodating vastly more passengers, while still keeping the trains running. Some say: don't change, civilization can be breached too easily; or, in the language of the train analogy, patch up the station a bit, but don't tamper with the basic structure. Others say: stop the trains; the building isn't worth saving; it's about to collapse; we need a clean field on which to build anew. That is the position taken by countercultures. If we think of them as art forms, we may find that, like other forms of art ranging from the sublime to the ugly, they highlight, dramatize and anticipate drastic problems. Whether as "voices crying in the wilderness" or as symptoms of major disorders—unintended warnings and illustrations of what may lie ahead—countercultures require the most intensive study by those whose aim and task it is to study societies and to see them whole.

"SITUATION" VERSUS "FRAME": THE "INTERACTIONIST" AND THE "STRUCTURALIST" ANALYSES OF EVERYDAY LIFE *

GEORGE GONOS
Rutgers University

American Sociological Review 1977, Vol. 42 (December):854-867

"Situation" and "frame," the elementary units of analysis of two versions of micro-sociology, are compared in order to elucidate the currently existing, but (as such) barely recognized, interactionist and structuralist approaches that they represent and to demonstrate that they contain widely divergent understandings of everyday life. After certain of the notions that underlie each of them are made clear, the contrasting positions of these two approaches are reviewed with respect to common issues, including the nature of the self, the place of meanings and subjectivity in analysis, and what are appropriate research methods. These considerations provide the basis for a general interpretation of Goffman's work, something the sociological literature has lacked. Though Goffman is most often treated as a symbolic interactionist, this paper argues that a better understanding of his work results from reading it as a version of contemporary structuralism. The fundamental ways in which his structuralism is distinct from the cultural (as well as the interactionist) approach also are given.

Micro-sociology, the attempt at a disciplined study of everyday life, has required that its theorists conceive of the "natural" unit of analysis for such a study, that is, the organized and bounded social entity most immediate to the individual's experience, within which his/her mundane affairs with others occur. This paper examines and compares two of the most significant of these conceptions—the "situation," as it is applied within symbolic interactionism, and the "frame," as conceived (most notably) by Erving Goffman—in order to demonstrate that they contain widely divergent understandings of the nature of everyday life. It is an exercise that must be seen as a fragment of what is necessarily a lengthier, more complex project that attempts to develop a truer and more comprehensive understanding of the body of Goffman's work, in part by proposing to view it as an American variant of contemporary structuralism and, consequently, by abandon-

ing the common misunderstanding that makes of Goffman a symbolic interactionist.

The initiate into American sociology might well come to know Goffman as a symbolic interactionist. That Goffman occupies a place within this school, sometimes as a major spokesperson, has been a frequent casual assertion in informal sociological talk and the (presumably) firmer conviction of many of those who make the classification of sociologists and sociological works their instrumental concern (e.g., Dreitzel, 1970:viii; Zeitlin, 1973:189ff; Mullins, 1973:76ff; Warshay, 1975:29ff; Eisenstadt and Curelaru, 1976:85,199,277; Cuzzort and King, 1976:240fn).¹ This paper asserts that when Goffman's work is forced into the symbolic interactionist paradigm and made to reflect, and speak to, its special concerns, much of the author's actual meaning and significance is lost, the result being some measure of distortion.² Such misreading

*Paper presented at the annual meetings of the American Sociological Association, Chicago, September, 1977. The following persons are thanked for their helpful comments: Tom Bamat, Dale Dannefer, Erving Goffman, Robert Kelly, Charles Nanry, Suzanne Paquin, Kathy Stanwick, Morris Zelditch, Jr. and two anonymous ASR reviewers.

¹ Many others make the assertion though it is not essential to their task (e.g., Denzin, 1972; Cole, 1975; Stokes and Hewitt, 1976).

² There are good sociological reasons to be found for this forced reading of Goffman's work within the organization and recent history of American sociology which, for lack of space, cannot be broached

conceals the fundamental and systematic differences between the theoretical character of Goffman's work and that of symbolic interactionism properly understood. These theoretical differences—regarding, for instance, the origin and nature of the self, the place of meanings and actors' subjective orientations in analysis, and what are appropriate research methods—surround issues of central importance, that is, those issues with respect to which symbolic interaction as a perspective has been defined by its leading figures (see Rose, 1962; Blumer, 1969). As will be seen, Goffman's approach stands opposed to the central tenets and most basic assumptions of symbolic interactionism.

Goffman's work from the beginning, has demonstrated not random departures from symbolic interactionism or mere idiosyncracies, but the application of an alternative paradigm.³ As opposed to the interactionist framework, Goffman proposes, albeit somewhat implicitly, his own version of a structuralist one.⁴ A structuralist reading of Goffman's work frees up for correct theoretical understanding most of the elements that have been seen in terms of author's style (or taken as superfluous) as well as those that previously have been misinterpreted or have simply gone unnoticed.

here. There are, it must be said, those commentators who refrain from applying the interactionist framework, at least in full, in their analyses of Goffman, and these are the better pieces (e.g., Gouldner, 1970:378–90; Glaser and Strauss, 1972; Manning, 1976). Yet these, too, fail to reach a general understanding of Goffman because they apply no alternative framework for interpretation and, therefore, remain impressionistic. Most often, some oddities are noticed about Goffman's work but they remain puzzles (e.g., McCall and Simmons, 1966:144–5). The resulting discussion of Goffman's work can be a confusing one (e.g., Collins and Makowsky, 1972:202–14).

³ It is not my intention to deny that important changes have taken place in Goffman's approach that some (e.g., Manning, 1976) have noted. This paper focuses on the central issues with regard to which Goffman has always been at odds with symbolic interaction. It might be said, however, that it is in *Frame Analysis* (1974) that Goffman most consistently takes the position ascribed to him here.

⁴ Certain commentators have begun to see this, notably Jack Douglas (personal communication) and Jameson (1976) whose excellent article suffers only from too great an association of Goffman with ethnomethodology.

In this paper, the constructs of situation and frame represent two opposing paradigms that are engaged currently in the study of everyday life, but each must be seen as the derivative of a classical sociological tradition. "Situation" is a password that opens up an interactionist (or social action) approach, the basic principles of which are Weberian, while "frame" poses an apparatus for a kind of structuralism for which Goffman is heavily indebted to Durkheim.⁵ The use within micro-sociology of these fundamental constructs activates many of the elements operative in each of these broader classical traditions, and multiple points of comparison continually suggest themselves. In this paper, most of these must be left undeveloped.

It should be clear that the identification and comparison of distinct theoretical approaches, such as the two in question here, is a project that requires some systematic method of its own. This study follows the suggestion of Bierstedt (1960:8) "to push [each] particular interpretation of social phenomena just as far as it is reasonable to go in our effort to shed illumination on it." What are presented, then, are idealized descriptions of each approach, which "candidly employ exaggeration" of their purity and exclusivity of orientation as an "heuristic device" (Bierstedt, 1960:8). This is seen as only a preliminary step in the overall effort to unify sociological knowledge, but crucial in order to avoid the common "facile synthesis" in which a reconciliation of perspectives is achieved at the cost of letting important differences between them go unrecognized. The point of our slightly

⁵ Unfortunately, in this paper, the links with these traditions cannot be made fully clear. This is an important task because micro-sociology has been thought of as a homogeneous field based on its presumed empirical domain, everyday life, and rejected or defended as a whole on the basis of the importance or triviality attributed to this interest. This atheoretical tendency should be counteracted by locating different micro-sociological theories within the greater theoretical paradigms to which they belong, that is, by showing to what theories of society they contribute. On this issue, this paper utilizes the recent work of Pope et al. (1975), which emphasizes the divergences, theoretically and methodologically, between Durkheim and Weber.

idealized codification of approaches, then, is to establish the actual nature of what are taken to be valid perspectives on the topic at hand. Only after such an effort is made can we hope for the working out of differences to produce a true synthesis, one that does not sacrifice the indispensable contribution intrinsic to either of the original partial approaches.

The Uniqueness of "Situations"

Symbolic interactionists have considered it their theoretical calling to describe the rich texture of everyday social life, a quality highly valued by them and, allegedly, coldly ignored in the functionalist portrayal of social reality, against which they define their movement (e.g., Scott, 1970). To remain true to human experience, they have insisted on study at close range, as participants, and, from this vantage point, the situations that make up everyday life have been seen as idiosyncratic.

Objective situations are unique. In the words of W. I. Thomas, "social situations never spontaneously repeat themselves, every situation is more or less new, for every one includes new human activities differently combined." (Stebbins, 1967:154)

The reward for research activity would seem to be an endless wonderment.

In fact, given this initial assumption about the uniqueness of situations, the abundant research energies of symbolic interactionism have cast it, as a body of work, in the direction of ever-more detailed description, that is, toward a vigorous empiricism. What concepts it has managed to generate have always been in danger of being rejected from within the paradigm by practitioners whose tactic to employ more precision (to appreciate more fully the rich texture, the "indeterminancy," of social life) undercuts attempts at generalization (e.g., Turner, 1962). The assertion that each situation is unique has been devastating of theory. Symptomatically, Blumer (1969:147) proposed that what he called the "definitive concept," that refers "precisely to what is common to a class of objects," give way in sociology to the less powerful "sensitizing concept" to prevent unwarranted

generalization. As he explained, "working with and through the distinctive or unique nature of the empirical instance, instead of casting this unique nature aside calls, seemingly by necessity, for a sensitizing concept" (Blumer, 1969:149).⁶

In contrast with the above-noted tendencies within interactionism, Goffman's work should be seen, in its essence and direction, as a formal sociology.⁷ This means that it is an effort toward the abstraction from everyday life of the very definite and limited number of forms or modes in which this life occurs. Goffman's goal, following a typical structuralist program-statement, is "the enumeration of forms and their organization, the exposition of signifying structures and their mode of functioning" (Lane, 1970:37); that is, the discovery of classes of objects, precisely the project Blumer rejects.⁸ There are not so many forms in which everyday life occurs that one will frequently be unrecognizable, its rules unfamiliar, to individuals who find themselves contained in it. Each of the forms of everyday activity studied by Goffman has a name: one is at the "movies," or the "dinner table." Note, however, that situations are nameless, but describable as, for instance, "the time Joe spilled his beans."

⁶ Compare Weber:

For the knowledge of historical phenomena in their concreteness, the most general laws because they are the most devoid of content, are the least valuable. The more comprehensive the validity or scope of a term, the more it leads away from the richness of reality for in order to include the common elements of the largest number of phenomena, it must necessarily be as abstract as possible and hence devoid of content. In the cultural sciences, the knowledge of the universal or general is never valuable in itself. (Weber, 1949:30)

⁷ Denzin (1972:88ff.) cites Goffman as offering a "formal sociology," yet his description of what constitutes formalism is, at least in the case of Goffman, misleading. Furthermore, his contention that interactionism itself tends toward formalism is, in the view of this paper, incorrect.

⁸ Thus, while Goffman's (1974:10) "aim is to try to isolate some of the basic frameworks of understanding in our society," Blumer (1969:148) would insist that "we do not cleave aside what gives each instance its peculiar character and restrict ourselves to what it has in common with the other instances in the class," thus precluding any such attempt.

While interactionists attempt to deal with the unfolding of actual everyday events, it is Goffman's intent to "see behind" this constant activity to what, in modern parlance, would be referred to as the "structures" that invisibly govern it. These structures Goffman now refers to as "frames," (and earlier as "occasions," and sometimes misleadingly as "situations"). Whereas a situation is described by its particular contents, especially by those elements that are unique to it and have been composed within its own existence, a frame is described by the stable rules of its operation, whatever the circumstances of any particular enactment. In other words, frames are not to be thought of as empirical in the way that situations are.⁹

In a structuralist analysis (here Goffman's), everyday life is seen to be made up of more or less well-delineated "worlds," realms of special meaning within which a particular language of reality is binding.¹⁰ The world is a mode of experience fleshed out by adherence to the rules of a frame or occasion.

Each class of . . . occasions possesses a distinctive ethos, a spirit, and emotional structure, that must be properly created, sustained, and laid to rest. (Goffman, 1963:19)

⁹ Godelier (1973:336) provides a clear exposition of this matter from the structuralist point of view:

"structures" should not be confused with visible "social relations" but constitute a *level of reality* invisible but present behind the visible social relations. The logic of the latter, and the laws of social practice more generally, depend on the functioning of these hidden structures and the discovery of these last should allow us to "account for all the facts observed."

Because of his use of innumerable empirical examples, Goffman is often thought to be interested in a sociology of appearances (e.g., Gouldner, 1970). But, though they possibly are excessive, I believe these examples are intended always to point up the relation between structure and action. In this regard, note Goffman's (1961a:35, 85) crucial distinctions between, for example, "game" and "play," or "role" and "role performance."

¹⁰ Alfred Schutz's analysis shares this method of dividing the subject matter into modes of experience that he calls "provinces of meaning," but Goffman (1974:3ff.) criticizes his handling of this job. The micro-sociologies of Schutz and ethnomethodology are not within the scope of this paper.

For Goffman, it is the world, not the situation-event, that is characterized by an analytically relevant uniqueness of cognitive and emotional style. Being in a particular world provides experience that is qualitatively different from that offered by any other world; merely different enactments of the same world are analytically indistinguishable. Goffman expresses this in an analysis of the worlds that the playing of games makes possible.

A matrix of possible events and a cast of roles through whose enactment the events occur constitute together a field for fateful dramatic action, a plane of being, an engine of meaning, a world in itself, different from all other worlds, except the ones generated when the same game is played at other times. (Goffman, 1961a:26-7)

If the structuralist analysis identifies well-defined worlds wherein action takes place, for the interactionist the substance of everyday life is much more homogeneous. The rules the interactionist sees operating in human interaction are universal, that is, are features of all interaction, not just that of any particular realm of activity. Furthermore, these rules are not discovered in research activity, but are starting principles, applicable to the study of any setting. In other words, they are not accurately referred to as rules at all but, rather, as laws. Basically, these are the Meadian principles that humans are symbolizing beings who, in interaction, make attributions and hold out expectations of others, who in turn amalgamate these to form a self capable of formulating meaningful reciprocal lines of action. This process, symbolic interaction, underlies all realms of human activity. What differs between settings and serves to generate interest within the interactionist paradigm is the varied character of social life that may be found and the different roles that are "played" by individuals, whose apparent naivete with regard to the facts of their cultural origin seems, from within the paradigm, to be notable.

Symbolic interactionism has looked to curious manifestations of its laws and, consequently, has been criticized for its picture of social reality that overemphasizes the "exotic" (Meltzer et al., 1975:98). Now we can see that this ten-

dency is *determined* for those working within the interactionist paradigm, who seek, quite naturally, to provide illustrations that will elicit high interest. The more exotic the behaviors of subjects appear to be, the greater the sense of irony generated by the seemingly blind identifications of these actors with their social roles. Barthes' examination of the "myth of exoticism" behind much popular ethnography lends support to this description of the similar habits of interactionist studies. In this sort of ethnography, he says, it is contended that "all things are alike, . . . they are only different in hue. . . . The cultural facts are never related to a particular historical order" (could we say particular world?). Rather, each example provides the means for emoting "the theme of an eternal condition" (Barthes, 1957:94-5). So it is that what varies for interactionists and makes things interesting, is not the set of rules that guides collective action in any setting, but the changing *contents* of human roles and situations.

In their descriptions of various subcultures that are built upon the pure laws of interaction, interactionists glide over the boundaries marking off the worlds that Goffman feels as stumbling blocks. He would consider the Meadian laws of symbolic interaction as something like truisms, which leave us as theorists in a seamless world whose apparent consistency defies real analysis. His work suggests that the apparent continuity of everyday life masks a real discontinuity, the coexistence of forms of daily life showing dramatic differences in principle. Their boundaries mark not just changes in taste or style, in how naked beings are clothed, but potentially significant differences in the character and quality of everyday life.

Thus, Goffman (1974:127) attacks the interactionists: "The first issue is not interaction but frame." Too easily, he says, "the term 'interaction' equally applies to everything one might want to distinguish," but this simple application "conceals the analysis that would be required to make sense out of this interaction" in the first place (Goffman, 1974:127). One cannot claim to have reached a scientific understanding of a strip of interaction,

says Goffman, unless one has worked out an understanding of the rules of the frame in which this interaction takes place. This latter understanding has been unconscious for the interactionists, who, like ordinary participants, have brought unexamined prior knowledge of background rules to the settings they have studied. Consequently, they have described variations of behavior within particular frames without acknowledging the set of rules and structured social relations that make the existence of such forms of activity possible.¹¹ To take Goffman's own example of this point, interactionists have gone to the theatre and studied such a phenomenon as performer-audience interaction without having come to recognize the system of conventions that brings into existence a "stage" (a new "plane of being") and a cast of "characters" who can behave without the ordinary consequences for their self-images.

Those who have studied the process of "defining the situation," then, mostly have ignored the micro-structures within which this informal, and (in a structuralist view) largely inconsequential, activity of defining takes place. But Goffman's study of everyday life has made these frames its focus. It asks about the central working principles that animate any particular mode of activity. "Frame analysis" is the attempt to become cognizant of the rules for cognition and communication that are bound up with the production of any world. Goffman's contribution to structuralism is his application of this method, almost unannounced, not to works of art or literature or to myth, but to the various "media" of everyday life, which constitute for him its different "genre" (Hymes, 1975), that is, forms of mundane activity characterized by stable rules of operation and understanding.

The Precariousness of "Situations"

Realizing that within a culture there is a great deal of uniformity in the manner in which particular activities are collectively

¹¹ See Godelier (1972:xv-xvi) for a terse account of the logically similar Marxist-structuralist critique of classical economics.

carried out—that a wedding, for example, is, in our society, always very much the same—interactionists have felt it necessary to make reference in their work to a distinction that is possible between “pre-determined” and “spontaneous” definitions of the situation (Thomas, 1972:332) or, in the same vein, between “rigid” and “pliable” ones (Stone and Farberman, 1970:150). Favoring the former pole of this distinction, there are those “role theorists” who have emphasized the cultural as opposed to the situational origins of these definitions. It will be necessary later in the paper to show why this concession does not make their analyses structuralist, as some commentators have suggested (e.g., Stokes and Hewitt, 1976).

For now, we should see that this tendency of some role theorists to emphasize the stable and cultural aspects of definitions resists the main pull of symbolic interactionism.¹² The insistence, by interactionists, on an approach focusing on “process” (e.g., Stone and Farberman, 1970:150, *passim*) has led them to favor the second pole of the above-mentioned distinction. Thus, as Stokes and Hewitt (1976:840) say, “The focus and strength of interactionist theory is an emphasis on people’s capacity to create meaning and order in the process of interaction.” The elementary unit of social life within the paradigm, the situation, is not constituted of imposed formal rules, but informal ones, devised from within for the duration of its short life. Its character, it is often stated, is ongoingly “negotiated,” always freshly accomplished. Seen as the ephemeral construction of social actors who are co-present and engaged in interaction, the situation is conceived as a *precarious* state. At any moment, it exists as a delicate and alterable balance of human (and physical) factors, the very “reality” of which can depend, we are told, on simple belief, i.e., its definition as real by participants.¹³

To Goffman, it is unthinkable that social reality might undergo a construction or reconstruction at every encounter. As opposed to the once-only understandings associated with situations, frames represent the worlds that are commonly “available” to members of a culture, and routinely “realized” through adherence to their conventions (Goffman, 1961a:41,28).

We cannot say the worlds are created on the spot because, whether we refer to a game of cards or to teamwork during surgery, use is usually made of traditional equipment having a social history of its own in the wider society. . . . (Goffman, 1961a:27–8)

The structure of a frame, unlike that of a situation, is fixed and left essentially untouched by everyday events. Thus, when some commentators (Gouldner, 1970; Collins and Makowsky, 1972; Manning, 1976) insist that Goffman depicts a social reality that is precarious and fragile, we must specify that it is the individual’s security and *sense* of reality that, in Goffman’s world, may be so described, not the social structure. Any world is an objective reality, whatever the status of its participants’ belief in it (Goffman, 1974:4–7). Variable definitions of this reality “contribute very marginally to the events in progress” (Goffman, 1974:1).

It is significant in this regard that Goffman sees the rules of frame as analogous to the syntactical structures of language (Goffman, 1974:11–2, 236). In this he shares a property crucial to most versions of contemporary structuralism, “the belief that all manifestations of social reality . . . that are practised in any society constitute languages in the formal sense” (Lane, 1970:13–4). The characteristic of language most salient to the present discussion is its stable and given structure. Its rules are left virtually unchanged by speech-events. Similarly, argues Goffman, social actors do not fiddle endlessly with the way their everyday worlds are built, nor need they explicitly recapitulate

¹² J. Turner (1974:151–92) makes the distinction between symbolic interactionism and role theory clear. Also see Robin (1974).

¹³ Peter Berger’s frequent usage of the word “precarious” to describe social reality is precisely this one, which is no accident. His work (Berger and

Luckmann, 1966:19) is also an attempt at “a sociological analysis of the reality of everyday life.” In that analysis, Thomas’ “definition of the situation” becomes Berger and Luckmann’s “definition of reality.” This serves to cast the analysis at a societal (rather than situational) level, but major portions of the interactionist conceptual apparatus hold.

the rules for understanding each time they act.

Presumably, a "definition of the situation" is almost always to be found, but those who are in the situation ordinarily do not *create* this definition, even though their society can be said to do so; ordinarily, all they do is to assess correctly what the situation ought to be for them and then act accordingly. (Goffman, 1974:1-2)

By ignoring frame, interactionists have had to hold to the position that nothing is understood by social actors that has not been communicated outwardly, or dramatized (e.g., Perinbanayagam, 1975). It is supposed that shared understandings surrounding every matter contingent to the actors' present project must begin in interaction, i.e., have an accomplished character. For Goffman, on the contrary, the basis of any realm of activity lies in a preexisting system of rules. It is simply inconceivable, from this point of view, that every element on which a situation is grounded be established within its bounds and, in the case of many of its features, not feasible because the actors' understanding is unconscious. Furthermore, to assume that any one such element could be defined in isolation from the others overlooks the systemic nature of the relations between them.

That the interactionists can think of situations as built up piece-by-piece is possible because these entities are thought of as constituted of an innumerable number of elements, amalgamated during the ongoing process of interaction, having no definite arrangement, and among them no relations of dominance. Stone and Farberman (1970:151fn) thus can tell us that they have thought of more than fifty such elements that make up a typical situation.¹⁴ These elements, they say, are "assembled, arranged, manipulated, [and] controlled" (Stone and Farberman, 1970:151) by participants in defining a situation. Any real-life situation is unique, then, because of its once only configuration of elements. And, within interac-

tionism, there will be no reference to certain of these elements as being ultimately determinant within any situation. Rather, a theoretical parity is assumed between them.¹⁵

From Goffman's analyses of particular framed activities, we can derive certain principle characteristics of frames. A frame is not conceived as a loose, somewhat accidental amalgamation of elements put together over a short time-span. Rather, it is constituted of a set number of essential components, having a definite arrangement and stable relations. These components are not gathered from here and there, as are the elements of a situation, but are always found together as a system. The standard components cohere and are complete; that is, together they represent a potential world that answers all questions about what it is that shall be taken by participants as real, and how it is that they should be involved in this reality. Other less essential elements are present in any empirical instance and lend some of their character to the whole, yet these are of necessarily minor importance relative to the basic configuration of components that govern the action. In all this, frames are very close in conception to "structures" as discussed by Piaget (1970) and Althusser and Balibar (1970).

As has been suggested, it is inherent in the nature of the task that interactionists have set for themselves—constrained by the imperative to demonstrate the emergence of definitions during interaction—that the situation be considered extremely malleable. In fact, because its members are granted a "nearly complete flexibility in the form and direction of conduct," the situation seems in conception to be infinitely variable. "The image conveyed is of [the] virtually limitless creation of culture" (Stokes and Hewitt, 1976:840). Since a situation entails no central principle of organization, no set of fixed relations at its heart, its participants presumably may redefine its loosely bound elements one at a time, incrementally changing its overall char-

¹⁴ Stebbins (1967:156,158) also refers to the "great many factors" that have a role in the composition of a situation, and he lists some of them. See also Stebbins (1972).

¹⁵ Compare Weber's very similar understanding of a historical "situation" as described by Aron (1970:235-47).

acter. A frame, though, would seem not to be subject to the gradual changes brought about by continued redefinition. Although change processes are very much under-examined by Goffman, a frame's invariant status implies that change occurs at some point by rapid mutation. With a great enough reworking of frame, we have done more than redefined a situation; we have destroyed a world.

"Structuralist" versus "Cultural" Orientations

I have referred to the emphasis placed by some role theorists upon widely-held cultural definitions of the situation, that is, on norms and values held collectively prior to the time a situation convenes. This is a viewpoint often termed "structural," and, sometimes, quite inappropriately, as we will see, as "structuralist," as, for example, in the recent article by Stokes and Hewitt (1976). In this section, I will discuss the important ways in which Goffman's approach departs from this "structural" or "cultural" one, even as it departs simultaneously from the interactionist approach (within which, incidentally, Stokes and Hewitt place Goffman with respect to their dichotomous "structuralist-interactionist" classification scheme).

Cultural definitions come about, it seems, from the accounts of some theorists, in the same manner as do the more ephemeral or situational kind, that is, through the interaction of individual social units. Thus, Stebbins (1967:158) speaks of them as having "developed from the interrelationship of many similar personal definitions." Such cultural definitions form the necessary consensus upon which any working social reality is seen to depend (Stone and Farberman, 1970:152; Perinbanayagam, 1974).

Frame analysis is in opposition to these views in at least two ways. First, "framing conventions," the set of rules governing an activity, are not seen as having arisen through a conscious, interactive process. Second, and more important in what follows, frame analysis rejects the picture of culture as given by role theorists, specifically the quality of near-perfect consis-

tency attributed to it when seen in the above-stated fashion—that is, as a large situation.

Within the cultural approach, the situations that embody a culture at any moment all reflect that culture's core values, as well as the principles of operation of the whole, which can be described as pluralistic. Each situation is seen as a mediating fluid between culture and the individual. It serves to transmit culture in two directions. First, it provides a medium of socialization where cultural norms and values materialize, i.e., are made real for the individual (Thomas, 1972). Hence, in this model, culture is ultimately the explanation of conduct as, within interactionism, it is the sum of the influences of co-present others (Stokes and Hewitt, 1976:839). Second, the incalculable number of situations serve as so many collecting devices for the inputs that individual actors make to the cultural "definition of the situation." In either direction of this flow, the transmission is true, clear and unimpeded.

The notion of frame allows Goffman a much different picture of culture and its consistency. Everyday activities are not simple reflections of the broader culture's organization and values. The boundary, or "membrane," between a focused activity system and the wider society is a screen which "not only selects but also transforms and modifies what is passed through it" (Goffman, 1961a:33). As Manning (1976:16fn) has noted, "since Goffman . . . sees the situated encounter as being 'tied' to the larger social structure through what he calls transformation rules, he does not adopt the Parsonian view that each relationship is patterned by a set of pre-established normative orientations." Though each framed activity is embedded in the organization of the wider society and owes its existence to the functioning of the whole, a close view of it does not provide a description of the greater system. There may be a difference, Goffman tells us, between, say, the distribution of substantive rights and power in a society and that which we find in the structure of a certain kind of encounter (Goffman, 1961a:34fn). Social action is contained, then, within micro-structures that have an

integrity as systems in their own right. Society is a "framework of frames" (Goffman, 1974).

What guides conduct in this structuralist model is not a set of shady core values or the influence of others who are co-present, but the individual's place within the formal social organization of a concrete activity, or, to put it differently, one's place with respect to the social relations of production of a ritual world. In comparison with this, an examination of Stokes and Hewitt's (1976) attempt to resolve the "parallel weaknesses" of the cultural and interactionist approaches must conclude that it offers no real alternative to these. Stokes and Hewitt simply give recognition to both "culture" and "others" as factors that influence conduct, thus paying homage at once to both the cultural and interactionist approaches, which, respectively, point to one of these two realities as that with which actions need be "aligned." Like these other approaches, they leave wholly unrecognized the structured "activity system" (or frame) within which everyday action, in Goffman's approach, takes place. In this way, Stokes and Hewitt succumb to the persistent belief that culture (meaning) and action are "all there is."

For the role theorist and the interactionist, then, culture is composed of activity-situations all operating on the same basic principles and carrying the same messages, reflections of one another and of the whole. But in the structuralist conception, each realm of activity exhibits, as a system, rules and understandings that may be in contradiction with those of other realms or with the greater society.

Where the social content of a situated system faithfully expresses in miniature the structure of the broader social organization in which it is located, then little change in the traditional role analysis is necessary; . . . But where a discrepancy is found, we would be in a position to show proper respect for it. (Goffman, 1961a:99)

In the structuralist model, it is in such discrepancy or incompatibility between the structures composing a system, where the potential lies for social transformation (Godelier, 1972:ix).

We can now see that role theorists who orient themselves to structure or culture and symbolic interactionists who emphasize process merely study from opposite ends what both see as a pluralistic and consensual society. Goffman's structuralism, while under the influence of both these other schools of thought, actually fits neither model and must remain misunderstood by those who would force it into one or the other.

Subjectivity and Meaning

I will return to the matter of exploring the divergence of the structuralist and interactionist approaches to the study of everyday life, now examining more traditional issues than those treated thus far: the place of subjectivity and meaning in analysis, and the ontological status of the self.

To gather the real importance of the role of subjective orientations within interactionism, it is helpful to return to the early development of this perspective. The formula known as the "definition of the situation" was conceived by Thomas in the 1920s in order to facilitate an understanding of the behavior of the individual social actor (Meltzer et al., 1975:22). It referred to the meaning an individual gave to his/her immediate circumstances, the interpretation one made of them. This definition was meant as one very important factor in the determination of the individual's behavior. Different behavioral responses could be seen as the result of variations in subjective definitions of the situation.

For the next generation as well, the focus of interactionism, in fact that of much of American sociology, remained "the person's behavior in the group" (Gorden, 1952:58), or "the relationship between . . . definition and behavior in the situation" (Stebbins, 1967:149).¹⁶ And, because it was the actor's subjective assessment of the situation that was seen as the most salient determinant of be-

¹⁶ Cottrell (1950:711) could say, in his 1950 presidential address to the ASA that, "Indeed, sociology can be thought of as a discipline devoted to the analysis of social situations."

havior, it was this mental construction that became the object of intensive study. Despite Thomas and Thomas' (1970:154-5) early warning that analyses should be done "not without regard to the factual elements in the situation," the "objective situation," as Stebbins (1967) termed it, came to be seen, quite inevitably, as negligible, since it was not to this unmediated reality that social actors responded (Perinbanayagam, 1974:523). It is the "subjective situation," stated Stebbins (1967:151), this "construction of the person's world, that is of concern to sociologists [because] it will affect [the individual's] action orientations." For his part, Stebbins (1967:151) announces what is usually implicit in interactionist studies: "In this paper the term situation will refer to the subjective kind unless stated otherwise." The tradition of interactionism had ruled out the objective conditions surrounding social action as a possible realm of scientific interest.

Interactionists, then, consider it to have been unquestionably established by their forebears that the starting point for any social analysis is the meaning that actors give to their situation. Thus, Perinbanayagam (1974:523) seems to feel that he is expressing more than just an analytical predilection when he states that "one is condemned . . . to a world of meanings." What he actually *does* express is the nature of his confinement within the interactionist paradigm. Of course, as Perinbanayagam suggests, an approach cast steadfastly at the level of meaning can be mobilized to an analysis of other than the behavior of individual actors within social situations:

We may fruitfully treat all human communicated material as "texts" (spoken, written, and I may add, carved, sculpted, painted, hieroglyphed, symbolized, emblemized, dramatized, filmed) and apply the same methods of interpretation and understanding. (Perinbanayagam, 1974:538)

But, if taken seriously, such an approach would entirely eliminate Goffman's present program of study, as outlined in *Frame Analysis*. For him, each of the above-mentioned media of expression presents a "code" (Goffman, 1974:7) to be cracked, an unconscious system of

categories and rules governing the creation and communication of meaning. It is the task of analytically recovering these grammatical systems that Goffman has set for himself. For him, the meanings transmitted via each of the media cannot be thought of as commensurate, as the quotation implies, for, implicitly contained within each, lies its more decisive "message," a formal system of social organization.

For interactionism, the focus on meaning is linked, as we have seen, to its conventional assumption that "everyday behavior is a 'direct' indication of [the actor's] inner state, of the doer's being" (Davis, 1975:601). Goffman, in the tradition of structuralism, inverts this understanding by making the subjective aspect of action subsidiary, an "after-effect." Any outward indication "is itself the substance, not the shadow" (Goffman, 1974:463).¹⁷ The actual pattern of determination, then, according to Goffman, is just the reverse of how, in our society (and in interactionism), it is perceived (Goffman, 1974:462-3). It is the activity of producing a particular world that generates a characteristic set of "inner states" for its participants. The pattern of their occurrence—when and for whom they shall be felt, as well as how they are to be expressed—is a determined aspect of the operation of any established kind of activity-system. Individuals infer the subjectivity proper to their roles in such a system by applying current doctrines concerning how they are to be related to their acts. Conventions regarding the nature of these "linkages" between acts and actors are a feature of the rules of any frame (see Gonos, 1976:200-1).

It follows from his estimation of the place of subjective orientations that Goffman's methodology necessarily differs from that employed in the study of situations. Because the situation is, in large part, a subjective reality, the means of its investigation lie most naturally in the Weberian method of *Verstehen*, the em-

¹⁷ Levi-Strauss (1963:68-70) similarly inverts the relationship between inner-states and their outward manifestations that he finds postulated in certain functionalist theories.

pathetic grasp of the social actor's understanding of the situation and his/her typical intentions within it. Documentation of these inner states may be sought through questionnaires, intensive interviews, or in natural dialogue.

Though for interactionists it is the only means of entry into the situation, Goffman does not wish for purposes of research to "take the role" of a participant in a setting (Goffman, 1974:8-10). Because his interest is largely in the unintentional properties (or syntax) of systems of activity, he can, for the most part, disregard what interactionists take to be the most important source of data, the meanings attached by actors to their situations. The rules for cognition and conduct by means of which an activity is actually produced and understood, as these are conceived of within structuralism, cannot be discovered in the consciousness of its participants, through an intersubjectivity. Thus, Goffman maintains a deep conviction about the uselessness of attending to actors' subjectivity and holds a special distrust of verbal admissions of motives.

When an individual speaks—formally or informally—sometimes what he seems to be doing is voicing an opinion, expressing a wish, desire, or inclination, conveying his attitude, and the like. These attestations of the existence of what are taken to be inner states have a relevant feature; they can be as little established as disconfirmed. (Goffman, 1974:502-3)

It is clear why Goffman's methodology, though following in its prejudices those of Durkheim, should seem mysterious, or even licentious, to some commentators. It is because his interest resides in what, for interactionists, is that forbidden terrain, the "objective situation" or, as MacIver put it, in "the situation as it might appear to some omniscient and disinterested eye" (quoted by Stebbins, 1967:150).

The "Self"

The interactionist perspective posits individual selves as the elementary, even the primal social entities, that is, existing prior to social structure. Mead, according to Blumer (1969:62), "saw the human being as an organism having a self." The

interactionist version of the "myth of creation" proceeds from the existence of selves (having certain predispositions) to the establishment, through interaction, of a social order. Situations and society are conceived of as "individual-generated" (Meltzer et al., 1975:24).

The starting point of this process, usually left unspoken, is called by Waller the "undefined situation," apparently not subject to any external constraints. For example, from Waller's *Sociology of Teaching*:

We see many undefined situations confronting the individual in the school. The new teacher confronts a situation wholly undefined, and he has very little idea as to the details of the definition that would be desirable from his point of view. The experienced teacher who faces a new class faces an undefined situation, and it is part of his job to impose his definition of the situation on the class quickly, before any alternatives have had an opportunity to be considered. (Waller, 1970:166)

Such a definition, Waller says, will establish, for example, whether the teacher will be "friendly" or "dominating" (Waller, 1970:166). Now, it is certainly true that such latitudes in work-style are allowed the schoolteacher and may indeed be discussed under the rubric of the definition of the situation.¹⁸ But, in the structuralist view, they must be thought of as fine points of adjustment within a system whose most fundamental rules are well-established and essentially nonnegotiable in our society, that of the classroom. This frame consists of a set of parameters for the student-teacher relationship, a peculiar conception of the nature of knowledge, a constricting system of grading and credit

¹⁸ It would be mistaken to understand the idea of frame as parallel in purpose to that of situation and, thus, as simply a substitute for the latter. Frame analysis retains a place for the notion of situation, as any concrete circumstance, but gives priority to the study of frames, which exist at another "hidden" level. Thus, in Goffman's analysis, factors are labeled "situational" that do not have a "continued consequence" (Goffman, 1974:426) beyond their present circumstances, in terms of frame. "[S]heer volume of commotion and furor is not what signifies, but again, it is frame relevance that counts" (Goffman, 1974:427). There is no equivalent distinction within interactionism.

which stratifies the student body and introduces power relationships, a customary physical arrangement, etc. Waller's approach, interactionism, effaces all this in beginning with a postulated "undefined situation" on which, presumably, actors may imprint their own notions of the classroom. Necessarily, then, Waller's description of the process of defining that ensues is surreptitiously narrowed in scope to focus on the teacher's actual rule-making capacity (see Waller, 1970:171). Consequently, the system of formal relations that is constituted by the classroom must go unexamined, while Waller, in the manner of interactionist studies, begins his analysis with nothing but selves.

Ultimately, then, the character of any situation is the result of the unique meeting of particular individuals and their combined effects on one another. In this conception, the sheer number of individuals present becomes important, as do arrivals and departures (Stebbins, 1967:153-8). Other individuals, not social structure or even norms, are seen as the greatest influence on social actors.

The attitudes of others are, in fact, the most important limitations upon the behavior of any one person, and they are also the most important inducements to any particular action. The attitudes of others are dynamic elements in the undefined situation which presents itself to any individual, and as a result of those attitudes the individual may come to define the situation in one way and not in another. Therefore we may say that one person defines the situation for another. (Waller, 1970:163)

In the interactionist analysis, then, differences in experience seem often to depend not so much on the realm in which interaction occurs as on whom an individual is with. The process of defining the situation consists of "the fitting together of the lines of behavior of the separate participants," resulting in what Blumer called "joint action."

For Goffman, everyday social encounters do not pose the problem of coordination, because they are examples of the ritualized reproduction of cultural objects according to preestablished formulae. Here, the primary forces exerted

on social actors do not come from other individuals.

The concept of interaction is thus transformed: instead of referring to mutual influence that might be peripheral and trivial, it now refers to a highly structured form of mutual fatefulness. (Goffman, 1961a:35)

For Goffman, say Glaser and Strauss (1972:457), "interaction proceeds to its termination almost as inexorably as a Greek tragedy."

Such imagery reflects the fact that a structuralist analysis, such as Goffman's, assumes a different starting point than that of interactionism. To employ one current means of expressing this, we can say that it does not "start with" social actors, but with the socially given frame that exists prior to these individuals, who are called upon to give it life. The language of frame analysis suggests that, in a very real sense, individual selves do not exist except for a tenuous social reality that certain frames bestow upon them. Self, here, is not an entity, as the interactionist perspective has it, but a dramatic effect. When and in what manner the self appears is an artifact of the operation of particular activity-systems, "not a result of some organic expressive carry-over from actor to actions" (Goffman, 1974:297). Goffman has, in different ways, always suggested that the appearance of self lies in a relationship, that it is conveyed through a discrepancy between structure and action (see esp. Goffman, 1961a:85-152; 1961b:320; 1974:293-300; Gonos, 1976:200-9). There is more than a hint that the issue of self only arises in our own historical epoch (Goffman, 1967:47-95). Far from grounding his analysis in the existence of individual selves, as is gathered by many commentators from a reading of the *Presentation of Self* (1959), Goffman has almost single-handedly among American micro-sociologists worked to undermine this possible grounding.¹⁹

The concepts "situation" and "frame" thus imply very different understandings of the place of the individual in analysis.

¹⁹ Note Balibar's similar determination to eliminate from social theory "as a foreign body" the idea of "men" (Althusser and Balibar, 1970:207).

Interactionists emphasize the world-building capacities of people in everyday situations and look to them as the source of social change, while the concept of frame leads Goffman to think of individuals as "supports" for the continued existence of social structures. They are "resources" or "materials" called upon to bring forms of activity to life: "human nature" simply "fits the frame" (Goffman, 1974:516).

Conclusion

Whereas interactionism objects to the "oversocialized conception of man" (Stone and Farberman, 1970:13) and emphasizes voluntarism, Goffman's individuals are aptly described as "sociological to the core" (Davis, 1975:601). What interactionists can be seen to glorify in sentimental manner as personal style, Goffman wishes to dignify as subject matter for a strict sociological analysis. Interactionism is charming because it retains a split picture for the analysis of everyday affairs and macro-social structures; thus, its easy coexistence with functionalism. Conversely, it is the understanding of daily activities as manifestations of social structure, a single picture so to speak, that enables Goffman to carry on his life-work, "to combat the touching tendency to keep a part of the world safe from sociology" (Goffman, 1961a:152)—a tendency, he suggests, that is very much alive within interactionism.

Goffman's work tells us that it is the reality of frame, not fashions of behavior, that the sociological study of everyday life must explicate, lest all modes appear to us as the same, as human interaction in different dress. It remains for us to analyze the place of the frames of everyday life within political and economic systems, the frames at another level of organization. This is the possibility that Goffman's work affords—the incorporation of micro-sociology into sociology proper.

THE FRENCH REPUBLICAN CALENDAR: A CASE STUDY IN THE SOCIOLOGY OF TIME *

EVIATAR ZERUBAVEL

University of Pittsburgh

American Sociological Review 1977, Vol. 42 (December):868-877

This paper is a sociological analysis of the most radical attempt in modern history to challenge the Western standard temporal reference framework, namely the French Republican calendrical reform of 1793. This reform obliterated the existing system of units of time and time-reckoning and dating frameworks by introducing a new annual cycle, new months, a new weekly cycle, a new subdivision of the daily cycle, and a new chronological dating framework. The paper first analyzes the symbolic function of the Revolutionary Calendar, namely, the representation of three main themes of the French Enlightenment: secularism, naturalism and rationalism. It then brings into focus three major factors which account for its failure: totality of the obliteration of the traditional sociotemporal order, overemphasis on secularization, and advocacy of nationalistic particularism at the expense of a practical and cognitive disruption of temporal coordination on a global level.

MODERN WESTERN STANDARD TEMPORAL REFERENCE FRAMEWORK

One of the fundamentals of social life is a *standard temporal reference framework* which is shared by all members of the society. Since time is among the major parameters of the social world, any social organization presupposes a coordinative calibration of subjective temporal references in accordance with a standard yardstick. Subjective temporal formulations such as "a while," "soon," "then" or "later" ought to be definable in terms which are accessible to others besides their user (e.g., "twenty-six minutes," "next Monday," "on May 19, 1977" or "at 10:45 P.M.'). This impersonal, collective, or intersubjective modality of temporal reference has been brought into sociological focus by both Durkheim (1965:23), in his discussion of a "time common to the group," and Schutz (Berger and Luckmann, 1967:26-8; Schutz and Luckmann, 1973:45-58), in his discussion of "standard time." The evolu-

tion of a standard system of units of time and standard time-reckoning and dating frameworks is quite parallel to the evolution of such systems as language, religion and law and to the transformation of subjective spatial formulations such as "here" and "there" into a standard grid system. They are usually internalized during primary socialization, and Defoe's satirical portrayal of Robinson Crusoe's habit of keeping track of the days of the week (and his naming of the first person he encountered "Friday") far away from civilization is highly suggestive of their coercive power once internalized.

The modern Western standard temporal reference framework¹ is based on the relatively universal relevance and use of the Gregorian Calendar, the Christian Era, International Standard Time, and clock time. It consists basically of the following two elements:

(1) *A standard system of units of time*
The year consists of 12 months or 365 days. Each cycle of 7 days constitutes a week. Days are divided into 24 hours, each hour into 60 minutes, and each minute into 60 seconds. All seconds are isochronal (that is, durationally uniform), as

* This is a revised version of a paper presented at the 71st annual meeting of the American Sociological Association, 1976, New York. I am grateful to Harold Bershad, Kai Erikson, Renée Fox, Charles Lidz, Victor Lidz, Braulio Muñoz and Yael Zerubavel for their critical and helpful comments.

¹ For some general sociological discussions of time and modern Western civilization, see Zerubavel (1976a; 1976b).

are minutes, hours, days and weeks. Of the twelve months of the year, seven are 31 days long, four are 30 days long, and one is 28 days (or 29 days in leap years) long. Every fourth year is a leap year and includes an additional day, the 366th.

(2) *Standard time-reckoning and dating frameworks* within which past, present and future events are standardly "localized" in time.² These frameworks are based on the following: (a) the standardization of time-reckoning by the clock and the institutionalization, in the 1880s, of *International Standard Time*; (b) a standard chronological dating framework, namely, the *Christian Era*, which takes the birth of Jesus Christ as a *standard temporal reference point* in relation to which events are "dated"; (c) a social convention, according to which days "begin" at midnight, months on the day called "—1st" and years on January 1.

Both our standard system of units of time and our standard time-reckoning and dating frameworks are social artifacts and, as such, by no means natural. The artificial origin of units of time such as the week, the hour, the minute or the second is pretty obvious. Yet even the year, the month and the day rarely correspond precisely to the periods of the revolution of the earth around the sun, the revolution of the moon around the earth and the rotation of the earth on its axis, respectively, but are, rather, "rounded" approximations of those. Moreover, the very selection of these natural cycles as the cornerstones of our system of units of time is in itself a *social convention*. Also, the fact that the temporal continuum does not naturally have any divisions along it suggests the conventional basis of our standard time-reckoning and dating frameworks as well. There is no "natural" reason for fixing the International Date Line and the boundaries between time zones where they are. Likewise, it is merely conventional that our era begins with the birth of

Jesus Christ, our year on January 1, our week on Sunday³ and our day at midnight.

The conventionality and relative validity of our standard temporal reference framework are among the basic arguments underlying Durkheim's (1965:22–8) critique of Kant's "apriorist" theory of knowledge and are also at the center of both Hubert and Mauss' (1909:213–9) and Sorokin's (Sorokin and Merton, 1937; Sorokin, 1943:171–97) characterizations of "social time." It also has been brought into focus time and again by comparative studies of non-Western calendrical, time-measurement and time-reckoning systems. However, an even better way of exposing the relative validity of the modern Western standard temporal reference framework would be to point out the changes made within it, since these imply that even within one and the same society it has no absolute validity and that it actually rests upon entirely arbitrary social conventions. Fortunately, history provides us with a fascinating case of a calendrical reform which spared almost none of the constituents of our standard temporal reference framework, replacing it with an entirely new one. Nevertheless, the fact that it did not survive longer than 13 years suggests that, despite its arbitrary and conventional basis, the standard temporal reference framework is deeply rooted in the culture, and its considerable organizational and cognitive centrality to social life may account for the resistance to any changes made in it. The following discussion is an analysis of the socio-historical significance of this reform and an attempt to account for its eventual failure.

² For some discussions of social frameworks of time-reckoning and dating, see Hubert and Mauss (1909:199–207), Halbwachs (1925), Sorokin and Merton (1937:623–26), Sorokin (1943:171–97), Roth (1963:1–13, 99–102) and Zerubavel (forthcoming: ch. 5).

³ Whereas the boundaries of the year, the month, the day or the hour are pretty clearly defined, there is some ambiguity with regard to the "beginning" of the week. According to the biblical and ecclesiastical tradition of Judaeo-Christianity, the week begins on Sunday, which is believed to have been the day of the creation of the world. However, though on most Western calendars the week is represented as a cycle which begins on Sunday, some ambiguity is introduced by the fact that the workweek begins on Monday. Thus, whereas Thursday is named "*Yom Hamishi*" (fifth day) in Hebrew and "*Quinta Feira*" (fifth market) in Portuguese (note also that the German name for Wednesday is "*Mittwoch*," which literally means "mid-week"), it is named "*Czwartek*" (forth) in Polish (see also Colson, 1926).

THE REFORM AND ITS SOCIAL MEANING

The reform which will be discussed here is the one associated with the French Republican Calendar (or the "Revolutionary Calendar"), which was in official use in France, its colonies, "sister republics" and annexed territories between 1793 and 1805. Based on a proposed recommendation by the Committee of Public Instruction,⁴ it was put into effect by the National Convention on November 24, 1793, and introduced the following changes in the standard temporal reference framework:

- (1) The establishment of a *new chronological dating framework*. The traditional Christian Era was replaced by the Republican Era, which began on September 22, 1792, the day on which the French Republic was founded.
- (2) The establishment of a *new annual cycle*. The traditional January 1 was replaced by September 22 as New Year's Day. Not only did the year on which the Republic was founded become a standard reference point for the new chronological dating framework, the day on which it was founded became a standard reference point for the new annual cycle.
- (3) The *uniformization of the months*. Unlike the traditional Gregorian year, which consisted of 31-day, 30-day and 28- (or 29-) day months, the Republican year consisted of 12 isochronal 30-day months. The five complementary days ("Sansculottides") were grouped together at the end of the year, as in the ancient Egyptian calendar. A sixth intercalary day was added on leap years ("sextiles"), which still fell every four years, although on the third—rather than the fourth—year of every group of four years ("Franciade"); that is, on years III, VII and XI, rather than on years IV, VIII and XII.

- (4) The *abolition of the seven-day week and Sunday*. Each 30-day month was divided into three 10-day cycles called "*décades*." Sunday was replaced by "*Décadi*," which was celebrated only every ten days, as the official rest day.
- (5) The *decimal subdivision of the day*. Days were divided into 10 hours,⁵ hours into 100 "decimal minutes" and "decimal minutes" into 100 "decimal seconds."
- (6) The introduction of an entirely *new nomenclature*. Aside from introducing new concepts such as "*Fran-ciade*," "*Sansculottides*," "*décade*," "decimal minutes" and "decimal seconds," the reformers renamed each day and month within the new calendar. The days of the "*décade*" were named in accordance with their numerical order as follows: *Primidi*, *Duodi*, *Tridi*, *Quartidi*, *Quintidi*, *Sextidi*, *Septidi*, *Octidi*, *Nonidi*, *Décadi*. The five "*Sansculottides*" were named after Virtue, Genius, Labor, Opinion and Rewards. The Catholic saints' days were abolished, and the days of the year were renamed after trees, plants, seeds, roots, flowers, fruits, farming implements and domestic animals. The new months were named after seasonal aspects of nature in the following manner: *Vendémiaire* (vintage), *Brumaire* (mist), *Frimaire* (frost), *Nivôse* (snow), *Pluviôse* (rain), *Ventôse* (wind), *Germinal* (seeds), *Floréal* (blossom), *Prairial* (meadows), *Messidor* (harvest), *Thermidor* (heat) and *Fructidor* (fruits).

It is hard to overemphasize the extent to which the reformers obliterated the traditional standard system of units of time and the traditional standard time-reckoning and dating frameworks, since hardly any component of those was spared. The scope of the reform was almost total, since its architects attempted not only to gain social control by imposing a new

⁴ For a complete protocol of the workings of this committee, see Guillaume (1894:437-51, 579-91, 693-713, 872-92). For some historical accounts of the reform, see Andrews (1931), Godechot (1951:363-6) and Herrmann (1938).

⁵ One implication of this was that watchmakers had to put new dials on timepieces that designated hours from "1" to "5," rather than "1" to "12."

rhythm of collective life, but also to bring about a *total symbolic transformation* of the standard temporal reference framework, as became an age pronouncedly devoted to total regeneration. As the fixing of leap years on the third—rather than the fourth—year of the *Franciade* suggests, these reformers were guided, in part, by none other than the considerations of the symbolic implications of introducing changes just for the sake of change. The Revolutionary Calendar was introduced in an age which advocated the total obliteration of the old order in the name of progress and modernity: the beginning of the new Republican Era marked the *total discontinuity* between past and present. In order to appreciate fully the social significance of this reform, which also accounts for the fact that the Revolutionary Calendar was re-adopted by the Paris Commune in 1871 (Mason, 1930:241), it is crucial to consider its *symbolic functions* within the socio-historical context of Revolutionary France.

Secularization

Ever since antiquity, calendars always had been closely associated with the religious sphere of life and, thus, totally controlled by the priesthood. In the particular case of pre-Republican France, the calendar in use had been actually introduced by Pope Gregory XIII and, thus, symbolically associated with the Catholic Church. In order to appreciate the symbolic significance of the Gregorian Calendar, one should note that, while Italy, France, Spain, and Portugal already had adopted it in 1582, it was not until 1752 that it was introduced into England, whereas Greece and Russia adopted it only after World War I (Ronan, 1974:603). The tremendous de-Christianizing effects of any reform of this calendar were pretty obvious. When Sylvain Maréchal proposed, back in 1788, to dispose of the saints' days as well as to abolish the seven-day week and Sunday, the Bourbon government ordered the destruction and burning of his influential *Almanach des Honnêtes Gens*, which it considered as "impious, sacrilegious, blasphemous, and tending to destroy religion" (Andrews, 1931:516). It is hardly

surprising that Maréchal opened his *Almanach des Républicaines* five years later with the following warning: "The calendar of the French Republic . . . must not resemble in any respect the official annuals of the apostolic and Roman church" (Andrews, 1931:525).

By introducing the Revolutionary Calendar, which was later condemned by John Quincy Adams not only as "superficially frivolous" and "coarsely vulgar," but also as "irreligious" (Lovering, 1872:350), the French Republic stripped the Church of one of its chief agents for exercising social control and regulating social life. The major thrust of the calendrical reform was against religion, and the new calendar was to be a civil one, divested of any ecclesiastical associations. More specifically, it was supposed to function as a de-Christianizer.

The Church's control of the *temporal regulation of social life* was challenged first of all by the abolition of the seven-day week and the replacement of Sunday by *Décadi* as the official rest day. Aside from the immediate symbolic significance of doing away with one of the most sacred elements within the Christian tradition, the introduction of the ten-day rhythm of social life played a major role in disrupting church-attending practices, since it presented both practical and cognitive difficulties in keeping up with the traditional, sacred seven-day cycle. It is interesting to note that an almost identical anti-clerical measure was applied nearly a century and a half later by Stalin, when he introduced the continuous five-day week (Moore, 1963:122).⁶ However, the replacement of Sunday by *Décadi* as the official rest day also resulted in a considerable reduction of the total number of rest days. That the new sociotemporal order involved working for nine—rather than six—days straight before having a rest day certainly did not help to increase its popularity.

Another act of de-Christianization was the replacement of January 1 by September 22 as New Year's Day. The temporal

⁶ Consider also the Fascists' attempts to secularize the calendar by introducing a civil, nonreligious rhythm of social life (Schneider, 1928:226).

continuum does not naturally have any divisions along it, and even though the annual cycle originated in a natural phenomenon, the decision as to where to fix the cut-off point that marks its "beginning" is a purely arbitrary one based entirely on social convention. It was Durkheim (1965:347) who maintained that it is the alteration between the sacred and the profane which leads man to "introduce into the continuity and homogeneity of duration, certain distinctions and differentiations which it does not naturally have." One of the major characteristics of any calendar is that it interrupts the continuous flow of time⁷ by introducing some regularly recurrent "*critical dates*" (Hubert and Mauss, 1909:197-208), and the events which constitute these standard temporal reference points usually have a particular symbolic significance within the society. In the particular case of the Revolutionary Calendar, a non-religiously significant event, namely, the foundation of the French Republic, was selected as the standard temporal reference point on which the annual cycle was based and, as far as secularization was concerned, that act had a most profound social significance. It was probably not practical convenience alone, but also symbolic considerations, that led Napoleon to restore the Gregorian Calendar beginning January 1, 1806, a totally meaningless date within the Republican Calendar, yet symbolically so significant (New Year's Day) within the restored one.

The Christian Era was replaced by the civil Republican Era as the standard chronological dating framework for precisely the same reason. It was time that separated the old order from the new one, and the beginning of the new age with a "new time" was to symbolize the total discontinuity between past and present. Since the flow of history is continuous, the selection of those historical events which mark the "beginnings" of chronological eras is a purely arbitrary

one. Usually these events are charged with profound social connotations, as the First Olympiad was to the ancient Greeks, the Creation of the World to the Jews, the foundation of Rome to the Romans, the Hegira to the Mohammedans, the March on Rome to the Fascists, and so on. As a most meaningfully-charged cultural symbol, the year 1792 seemed to be a perfect choice for the new "point of departure" and the fact that, although the establishment of the new era was decided upon only in 1793, it began retroactively in 1792, attests to the particular symbolic significance of the latter. The substitution of the date of the foundation of the French Republic for that of the birth of Christ as the standard temporal reference point of the new era symbolized the de-Christianization of the standard dating framework. It implied that France had entered a new, secular age, in which the foundation of the Republic was to be regarded as far more historically significant than the beginnings of Christianity.

Naturalization

A purely physico-mathematical analysis of the Revolutionary Calendar, which would ignore the poet Fabre d'Églantine's nomenclatural innovations, would never provide us with an adequate basis for grasping its full social meaning. Within a sociological perspective, which recognizes the great extent to which names are charged with meaning (Cassirer, 1953:44-62), calendrical systems ought to be regarded as products of the interaction between mathematical divisions of time and symbolic frameworks of meaning. It is in this light that one should view the naming of the new months after seasonal phenomena,⁸ as well as the abolition of the Church's saints' days and the renaming of the days of the year after phenomena in Nature instead. The new calendar was to symbolize the centrality of natural phenomena to the life of the new society, thus expressing the belief of the French Enlightenment in the need for

⁷ For an empirical study of the way in which the continuous flow of time is interrupted through the introduction of *social cycles*, see my analysis of the rhythmic structure of organizational life (Zerubavel, forthcoming: ch 1).

⁸ Consider also, in this regard, the Nazis' attempt to substitute Teutonic archaisms for the names of the months (Grunberger, 1971:446).

man to be in harmony with Nature. In the case of the months, names were designed so as to suggest Nature in a way that even transcended their mere referential function. By means of a morphological device, namely a differential application of suffixes ("aire," "ôse," "al" and "dor"), both the rhythm and the tone of these names suggested that they were grouped in four distinct three-month blocks, each of which was associated with a particular season. Thus, by both semantic and morphological means, the new nomenclature established a seasonally-based differentiation between the months, symbolizing the unbreakable bond between the *social* calendrical system and the cycles of *Nature*.

One of the most remarkable accomplishments of the calendar reformers was exposing people to the naked truth, that their traditional calendar, whose absolute validity they had probably taken for granted, was a mere social artifact and by no means unalterable. However, the reformers must have realized the possible boomerang effects of that, since it was impossible to expose the conventionality and artificiality of the traditional calendar without exposing those of any other calendar, including the new one, at the same time. One could not help realizing, for example, that if the seven-day week did not derive from the heavens and was merely an arbitrarily imposed convention, so was the ten-day *décade*. The new calendar could not be viewed as absolutely valid, since its users witnessed its birth and knew that things used to be different in the past.

Nevertheless, upon introducing the Revolutionary Calendar, its architects attempted the nearly impossible, namely, convincing their contemporaries that calendars in general were merely conventional artifacts (to account for the disposability of the traditional calendar), yet that their new one was not! However, in order for the Revolutionary Calendar to be accepted as absolutely valid, it first had to be viewed as an inevitable development and by no means a mere arbitrary convention. The reformers' way of achieving that was by associating their calendar with Nature. In order to suggest that it reflected

the natural order and drew its authority from it, the new months were named after seasonal phenomena. Along the same lines, a symbolic association between the new social order and Nature was attempted through the use of the co-occurrence of the foundation of the French Republic and the autumnal equinox. Though it was probably a mere coincidence that this unique historical event took place on a day which happened to be so significant in Nature, the reformers nevertheless could legitimize their choice of September 22 as the principal temporal reference point in the new calendar on the basis of establishing a harmony between the social and the natural. The symbolic implications of the multiple significance of this date—on which the sun also entered *Libra*, which is symbolically associated with equality—did not escape the attention of the calendar reformers. When it proposed to synchronize the annual social cycle with a cycle which derived from the rhythmicity of Nature, the Committee of Public Instruction stated explicitly that "the equality of the days and nights was marked in the heavens at the same moment when civil and moral equality was proclaimed by the representatives of the French people as the sacred foundation of their new government" (Andrews, 1931:526-7).

Rationalization

In order to establish the legitimacy of the new system of units of time, the reformers also tried to make it more "rational" and "scientific" through the application of the *decimal system*. Whereas calendars traditionally had been designed by the priesthood, the Revolutionary Calendar was intended to be an unprecedented project rationally designed and adhering solely to the principles of Reason and Science, as advocated by the French Enlightenment. Accordingly, its chief architect, Charles-Gilbert Romme, was a former professor of physics and navigation, whose consultants included scientific authorities such as the mathematicians, Monge and Lagrange; the astronomers, Lalande and Pingré; the chemist, Fourcroy; and other

distinguished members of the Academy of Sciences. It was no mere coincidence that Monge and Lagrange were also members of the committee who had introduced, only a year before, a major reform of the system of weights and measures. In fact, the calendrical reform actually was viewed as an extension of the metric reform, and, accordingly, it adopted the *decimal principle* as the basis of the new system of units of time. The act of adopting the very basis of our counting system in order to systematize the relations between the new weeks, days, hours, minutes and seconds involved much practical convenience,⁹ yet it also had some important symbolic implications as well. Just consider the religious connotations of the number "7" within the Judaeo-Christian tradition, for example, and, on the other hand, the rationalism and scientism associated with the decimal principle, which is among the cornerstones of Western mathematics.

A similar attempt to associate the new calendar with Reason was the naming of the days of the *décade* according to their numerical order. This act symbolized the replacement of the qualitative conception of time—which was associated with the traditional, religious and nonrational—by a *quantitative* orientation towards it, as became an Age of Reason. The new units of time were regarded as certain "quantities" of duration, which were systematically related to one another in mathematical terms, namely, as multiples of one another. With the abolition of the saints' days, Sunday and the Church's religious holidays, the days of the week and the year lost much of their unique character and, as mathematically equal entities, they became far more interchangeable with one another.

The *systematization* of the relations among the various units of time was also furthered by the uniformization of the months and the replacement of the seven-day week by the ten-day *décade*. Aside from saving the users of the new calendar the trouble of memorizing the

number of days in the various months of the year, the reformers also accomplished an unprecedented concordance of monthly and "weekly" cycles by establishing a mathematically regular relation between the month and the *décade*. Within the Western standard temporal reference framework, the weekly and monthly cycles are based on incompatible rhythms, since the former runs independently of the latter. Whereas years consist of a number of *complete* months, so that the beginning of a year coincides with that of a month,¹⁰ weeks do not have to be "completed" in order for a new month to begin. The implication of this for everyday temporal reference is that "weekly" and "monthly" dates are independent of one another, so that a calendar is necessary in order to reckon on what days of the month Thanksgiving Day, Election Day or Labor Day fall, or on what day of the week Christmas falls, in any given year. In the French Republican Calendar, however, the fixed mathematical relation between the month and the *décade* (1:3) made the *synchronization* of these two cycles possible through fixing the beginning of the month on *Primidi*. The user of this calendar could convert dates which were formulated in terms of the day of the month into dates formulated in terms of the day of the *décade*, and vice versa, simply by referring to the last figure of the former or the mere name—which also reflected the numerical order—of the latter. The tremendous contribution of this simple, yet sophisticated "rational" arrangement to everyday temporal reference can hardly be overemphasized.

THE FAILURE OF THE REFORM

As it turned out, the French Republican Calendar did not prove to be a success and, on January 1, 1806, the Gregorian Calendar was restored by Napoleon. One main reason for the failure of the calendrical reform was probably its overemphasis on the totality of the obliteration of the

⁹ For a discussion of the convenience involved in applying the decimal principle to social organization, see Simmel (1950:171-4).

¹⁰ The same is true about the relations among months, days, hours, minutes and seconds. As Colson (1926:2) has noted, the seven-day week is the only "intruder" in this ordered system.

traditional system of units of time and time-reckoning and dating frameworks. Given the popularity of any standard temporal orientation, it is quite likely that the reformers would have been far more successful had they incorporated parts of the old sociotemporal order into the new one. By suggesting some symbolic continuity between the two, they would probably have contributed to further the *legitimacy* of the new system. As the recent case of the transformation of the meaning of the British "penny" (in terms of its mathematical relation to the £) while preserving its traditional name suggests, such an approach might have avoided hurting traditionalist sentiments, thus facilitating the acceptance of the new symbolic order. However, the metric reform of the system of weights and measures, which was introduced in France at about the same time, clearly achieved a tremendous success despite its absolute obliteration of the traditional order. While very few people today are even aware of the fact that the French Republican calendrical reform ever took place, the metric system is still in use at the present time, not only in France, but in most of the Western world. The failure of the calendrical reform is even more striking, therefore, when contrasted with the success of its sister reform, and it certainly cannot be fully accounted for only by the totality of the obliteration of the old order.

The calendar reformers' overemphasis on secularization was another major factor which probably hindered their potential success. When we contrast the failure of the Revolutionary Calendar with the tremendous success of the metric system, we must remember that the Revolutionary Calendar had to challenge the existing symbolic order associated with the sacred—such as disposing of Sunday and the Church's saints' days—whereas the metric system did not have that problem.¹¹ The fact that the restoration of the Gregorian Calendar by Napoleon was

actually a part of his general reconciliation with Rome clearly suggests that the failure of the calendrical reform must be viewed within the context of the overall failure of the French Revolution to de-Christianize France. The reformers must have underestimated the depth to which religious sentiments were still rooted among the French people, many of whom probably found it impossible to depart so abruptly from a traditionally sacred symbolic order which had been taken for granted for centuries.

Another major factor which proved to be detrimental to the calendrical reform's chances of survival was its pronounced *particularistic* spirit, which was manifested in the nationalistic symbolism of names such as "*Franciade*" and "*Sansculottides*" and dates such as "September 22" and "1792." The symbolic function of introducing a unique system of units of time and unique time-reckoning and dating frameworks is very similar to that of introducing a unique national anthem or flag.¹² However, whereas a multiplicity of national anthems or flags does not generate any confusion or inconvenience which might hinder international communication, a *multiplicity of temporal reference frameworks* certainly does. There was no way to synchronize the Revolutionary and Gregorian time-reckoning and dating frameworks, and any date within the former was totally meaningless to users of the latter in other countries. The days of the *décade* could not correspond to those of the week, since these two functionally analogous social cycles were based on totally incompatible rhythms. As for the numerical names of the days of the Revolutionary and Gregorian months, although these two cycles were based on very similar rhythms, their beginnings did not coincide, and all the Revolutionary months began sometime around the 20th day of the Gregorian month. Finally, the numerical expression of the Revolutionary year was also mean-

¹¹ It is interesting to note, however, that those societies in which the metric system has not yet gained a stronghold tend to cling to their non-decimal monetary, measure or weight systems as sacred symbols of their traditions.

¹² To take the case of the Jewish Calendar in modern Israel, for example, most of the debates over whether to keep it revolve around the nationalistic symbolism involved in a unique standard temporal reference framework.

ingless to anyone who did not consider the foundation of the French Republic the most significant event in history. Even the official *Moniteur* had to insert the Gregorian date in brackets after the Revolutionary date (Andrews, 1931:528, 531n), and contemporary historians must use concordance lists (Herrmann, 1938) in order to "translate" Revolutionary dates so as to locate them in conventional chronology.

That the calendrical reform entailed France's international isolation, whereas the metric reform did not, need not surprise anyone who appreciates the functional uniqueness of the clock and the calendar in Western civilization. The remarkable sophistication in the popular development of time-measurement and time-reckoning devices in the West has no parallel in the domain of measures and weights, and most children are introduced to the clock long before they learn how to use a ruler or a scale. Whereas spatial markers such as maps, train stop and street signs, and elevator floor indicators are needed only upon relocation in space, *temporal markers* such as watches and desk calendars are referred to much more frequently due to the inevitability of our constant mobility in time. Modern social life would have been impossible without *temporal coordination*, which presupposes a generally accepted standard temporal reference framework.

Thus, it may very well be that the French Republican calendrical reform was also less successful than the metric reform in gaining popular acceptance because the abrupt transformation of the standard spatial reference framework threatened modern social organization less than did that of the standard temporal reference framework. The reformers challenged the latter when it was already adopted by most of the Western world, in an age when international communication already presupposed temporal coordination on a global level. It was that factor, as well as the reformers' overemphasis on total obliteration of a traditional sociotemporal order symbolically associated with the sacred, that spelled doom for the French Republican Calendar. It should be noted that its eventual abolition actually marks

the failure of the most radical attempt in modern history to challenge the Western standard temporal reference framework, which is, until this day, among the cornerstones of modern social life.

CHINESE CONSUMPTION OF FOREIGN COMMODITIES: A COMPARATIVE PERSPECTIVE*

GARY G. HAMILTON

University of California, Davis

American Sociological Review 1977, Vol. 42 (December):877-891

A recurrent theme in the literature on modernization is the importance of Westernization in non-Western societies—the purchase of Western commodities and the emulation of Western styles. This paper critically examines this theme in relation to a negative case, the lack of Westernization in nineteenth-century China. Three different theories of consumption that have been offered to explain the nonacceptance of Western products in China—an economic theory, a cultural theory and a sociological theory—are analyzed from comparative and historical perspectives. On the basis of this analysis, it is suggested that Westernization during the nineteenth century can often be viewed more accurately as an indicator of stratifactional continuity with the premodern era than as an indicator of modernizing changes.

With considerable justification, Karl Marx and many later writers believe that a decisive factor in the nineteenth-century expansion of Western civilization was the distribution of commodities produced by capitalist factories. Marx (1959:11) says, "Cheap commodity prices are the heavy artillery with which [the bourgeoisie] batters down all Chinese walls and forces the barbarians' intensely obstinate hatred of foreigners to capitulate. . . . It compels them to introduce what it calls civilization into their midst, i.e., to become bourgeoisie themselves. It creates a world after its own image." Nowadays, students of society seldom accept such simplicity in their explanations. Nonetheless, most recent theories recounting the economic factors of modernization prominently in-

clude, as a causal mechanism, the distribution and sale of Western products in non-Western societies. The more sophisticated theories no longer rely exclusively on the difference in price between factory-made products and handicraft goods. Instead, they emphasize such factors as the restructuring of market relationships (e.g., Smelser, 1963), the establishment of primary trading cities (e.g., Murphey, 1969) and the subordination of non-Western producers (e.g., Frank, 1967)—all of which are subsidiary to the creation of a world marketing system (Wallerstein, 1974; Eisenstadt, 1973). Despite such insightful and justified elaborations, *one* of the causal mainsprings by which this process of Western expansion *began* remains the non-Western consumption of Western goods.¹

* A revised version of a paper presented at the annual meeting of the International Society for the Comparative Study of Civilizations (US), April, 1976. I am indebted to Ben Orlove, C. K. Yang, Pierre van den Berghe, Benjamin Nelson, Gilbert Rozman and two anonymous reviewers for their useful comments on the earlier version of this paper.

¹ This causal mechanism is illustrated in such studies as Wallerstein's (1974), where Eastern Europe (the periphery) buys manufactured commodities from and sells agricultural products to Western Europe (the core), and Gallagher and Robinson's (1953), where England builds an informal

Granted the ubiquity of this causal theme, surprisingly little is known about the factors influencing non-Western use of Western commodities.² This paper will explore some of these factors by focusing on what is regarded by many as a negative case—nineteenth-century China. It is well-known that the Chinese, during the height of Western commercial expansion (1860–1930), did not consume Western products readily or abundantly. It is equally well-known that the lack of Western influence in China goes far beyond the non-consumption of a few factory-made commodities. In fact, some suggest that, of all the non-Western agrarian societies in the nineteenth century, China was the least influenced by the impact of Western civilization (e.g., Jacobs, 1958; Nathan, 1972; Murphey, 1974). Concentrating on a very narrow aspect of this impact (i.e., the lack of interest in Western products) can (1) suggest some factors that influenced the acceptance of Western commodities in non-Western societies and (2) evaluate some approaches towards understanding larger, and obviously more complex, issues of Westernization during the nineteenth century.

Three sets of explanations will be outlined; each attempts to account for Chinese lack of interest in Western commodities: the “faulty marketing and merchandise,” the “culture” and the “status competition” explanations. The “faulty marketing and merchandise” explanations contend that Western products could not overcome the competition of the traditional economy; hence the Chinese, being rational consumers, wisely purchased Chinese products. The “culture” explanations assert that China possessed a pervasive, socially integrating culture, whose

symbols were known and approved by all; hence the Chinese, being highly ethnocentric and xenophobic, exclusively consumed tokens of their own culture. Nineteenth-century observers and modern scholars primarily use one of the two or both to explain Chinese non-consumption of Western goods. The “status competition” explanation—very rarely, and then only implicitly encountered in the sources—maintains that the Chinese conception of high social status was more influenced by local and rural than by national and cosmopolitan standards; hence the Chinese preferred to consume commodities having established meanings of social status rather than those having exotic symbolic content. Each of these explanations will be examined from a comparative perspective in order to judge their usefulness in explaining the Chinese case. In order to approximate roughly the range of conditions within Chinese society, I will limit my comparisons to non-Western agrarian societies.

Limited space will confine my explanation to the non-Westerners’ consumption of Western-made, primarily British, textiles. This choice is advantageous. Textiles rank as the most prominent export from nineteenth-century capitalist factories; textile production laid the initial industrial foundation for England and for other Western societies; and, most important, because the Chinese did not purchase much Western cotton, the Blackburn Chamber of Commerce (composed of Lancashire textile manufacturers) commissioned an investigation to discover the reasons. The report from this investigation gives the most detailed information available on the conditions of the textile trade in the interior of China.³

empire out of non-colonialized countries (e.g., Latin America) by maintaining commercial suzerainty over the territory, thus ensuring an overseas market for British goods.

² The lack of interest in this area can be explained, in part, by the sociologist’s general lack of interest in the process of consumption. As Smelser (1976:131–40) remarks, “consumer behavior” typically has been a topic of interest only for economists. There are, of course, some exceptions. Besides those sociologists mentioned below, Veblen (1953) and Fallers (1966) provide notable contributions to the sociology of consumption.

³ The Blackburn Commission traveled some 4,300 miles through the interior of south and central China between October, 1896 and June, 1897. They collected detailed information on all factors relating to how the Chinese met “their own wants in the matter of textiles” including material on marketing, distribution, indigenous handicraft production, taxation and “local customs and usage as they might affect our textile industry” (Neville and Bell’s Section, 1898: Preface). The report was published in two lengthy sections, one written by H. Neville and H. Bell and the other by F. S. A. Bourne, a member of the British Consular Service, under the title, *Report*

*The Consumption of Foreign
Commodities during the Ch'ing*

That the Chinese did not purchase large quantities of Western products in the nineteenth and early twentieth centuries is a well-known fact. The extent to which the Chinese did not buy Western goods is not so well-known and bears repeating briefly.⁴

One of the few quantitative measures of the consumption of Western products is the record of imports entering through specific trading centers. When used as an indicator of Chinese consumption, such statistics, even if completely reliable, represent the maximum figure possible. For China, however, these statistics are known to be greatly inflated for several reasons. First, because of extensive transshipment of goods between reporting stations, there is a significant but unmeasured amount of duplication in the figures. Second, Westerners and their staffs, who lived in the treaty ports, purchased a sizable portion of the imports. Third, as more treaty ports opened, the statistical coverage included previously unreported imports, thus exaggerating the rate of growth. Fourth, the value of imports was reported in Chinese taels, whose value declined between 1870 and 1930 by about two-thirds. Fifth, nearly a third of the total imports into China after 1920 went to Manchuria, a separate economic system developed and tightly controlled by the Japanese. Last, drug and foodstuffs from Southeast Asia—such as rice, birdnests and sharkfins—constituted between twenty to thirty percent of the total amount of imports.

Based upon these qualifications, Murphey (1974:48–9) estimates that, although recorded foreign imports increased between the years of 1870 and 1930 by a factor of thirty, the actual increase was “perhaps three or four times at most.” Even if the statistics are not corrected to take these factors into account, the total dollar amount of imports places China on

par with such countries as “Mexico, Chile, New Zealand, Brazil and the Union of South Africa, and far behind Argentina, Australia, Canada, Denmark, the Federation of Malaya, India, Indonesia, or of course any of the industrialized countries of the West, or Japan.” If these figures are computed in terms of per capita consumption, then Murphey’s assessment is not an exaggeration: “China’s importation of foreign commodities remained negligible, and even at its peak probably smaller than that of any country in the world, including Tibet.”

*The Faulty Merchandise and Marketing
Explanations*

Although composed of many separate explanations, the faulty merchandise and marketing explanations category has a central theme: Western products were simply unable to overcome the competition posed by indigenous products. An important corollary to this theme maintains that the imposition of Western imperialism in China was incomplete. Western powers did not colonize China. Although they divided China into vast “areas of influence,” Westerners lived in only a few coastal cities, such as Shanghai, and in China’s capital, Peking. They did not disrupt the existing organization of the Chinese economy and used traditional means to market their products.

In elaborating this theme, the faulty merchandise and marketing explanations cover two overlapping, but analytically distinct, areas: (A) Western products were more expensive and of poorer quality than comparable handicraft products. (B) The traditional commercial system hampered the distribution and marketing of Western products.

(A) Many analysts believe that the principal reason Western cottons sold poorly in China was that handicraft cottons were cheaper and better suited to the needs of the Chinese (Cooke, 1858:187; Neale, 1862:383; Nathan, 1972; Reynolds, 1974). The evidence presented by the Blackburn Commission, based largely on interviews and observations, seems to support this explanation. The Commission observed (Neville and Bell’s Section, 1898:256) that

of the Mission to China of the Blackburn Chamber of Commerce.

⁴ For these comments, I am closely following the discussion of Murphey (1974:47–9); also see Feuerwerker (1969).

the majority of Chinese, the peasantry, engaged in outdoor manual labor and, therefore, required durable, warm clothing. Because they were tightly woven, using a fine thread, Western cottons lacked the durability and warmth of the coarser native cloth. A smart consumer, they reasoned, would purchase native cottons. Many modern students of China follow the same line of reasoning, describing the Chinese peasant as a "rational economic man": "A great deal of the Chinese reluctance to buy foreign goods or to adopt foreign business methods or technology was *entirely rational and not culture-bound*: traditional Chinese goods and methods were equal or superior, especially in cost terms" (Murphey, 1974:30, emphasis added).

The quality of native cotton notwithstanding, the Blackburn Commission was especially concerned about its cheapness in comparison with the cheapest lines of Western fabrics. In seeking an explanation for this, the Commission made what they considered to be an important discovery: the relative cheapness of native cottons was the result of the importation of huge quantities of inexpensive cotton yarn from Indian cotton mills in Bombay (Neville and Bell's Section, 1898:210-9, 234-5). The availability of this yarn had caused a "revolution" in weaving (Neville and Bell's Section, 1898:271). Wherever they traveled, the Commission found cotton handicraft industries, which once had been concentrated in the cotton-growing regions of the Yangtze river basin, spreading throughout China. Much of the increase in production, they discovered, was not for home consumption but was for sale in the marketplace. In some areas, such as South Yunnan, the Commission found that most of the local population, long accustomed to buying cloth in the marketplace, did not know how to weave before Indian cotton yarn became available. But with the importation of this yarn, many attended classes in weaving in order to take advantage of the sudden opportunity to profit from handicraft production (Neville and Bell's Section, 1898:261-6). This increased the supply of handicraft cottons, causing their price to decline.

This explanation is appealing, for it would tend to support the contention that factory-made commodities were purchased because they were cheaper than handicraft goods, but when they were more expensive, they were not purchased. Hence in China, the exceptional society in which Western commodities were more expensive, they did not sell.

There are, however, some shortcomings to this explanation. It is questionable whether handicraft products, especially textiles, in other non-Western agrarian societies were more expensive than Western goods. Although information is limited, we do know that handicraft industries in many societies survived the nineteenth century and, indeed, some survive even today.⁵ The important point here is not the cheapness of the commodities but who consumed them. The above explanation is designed to explain why the poorest Chinese, the peasants, did not buy Western fabrics. But in other non-Western agrarian societies were peasants *the first, the only, or the most likely* consumers of Western fabrics? Platt (1973:82) maintains that during the nineteenth century, "For Latin America a large part of peasant consumption was met by home weaving, in cottons and especially in woollens. . . ." Morris (1968) makes the same observation for India. Based on this, it seems plausible that, in those societies where peasants lived more on the edge of subsistence than they did in China⁶ and where the marketing system was less developed than it was in China, peasant populations would be even less likely to consume Western fabrics than were Chinese peasants. Moreover, based

⁵ For example, considerable handicraft production continues today among the highland Indians of Central and South America (Orlove, 1974), throughout sub-Saharan Africa (Plumer, 1971), in Indonesia (Adams, 1969), in Thailand (Ingram, 1955:118-23) and in India (Gandhi, 1931; National Council of Applied Economic Research, New Delhi, 1959; Morse, 1908; Raychaudhuri, 1968).

⁶ Although the point is certainly subject to debate, recent research is showing that the Chinese per capita income was quite high by world standards, perhaps as high as that in any society in the world prior to the Industrial Revolution. See, for example, Murphey (1974:32-43), Myers (1970) and Perkins (1969).

on ethnographic data, one has every reason to think that a great many peasants, Chinese and otherwise, would not be disposed towards the use of Western fabrics. For instance, we know that in many places, peasant communities often used distinctive textile designs to differentiate their work from that of other peasant communities (e.g., Primov, 1974). Nineteenth-century Western manufacturers did not attempt to imitate *most* of those designs.

This explanation seems even less reasonable, then, if one hypothesizes that it was the richer, not the poorer members of non-Western societies who were the first, and continued to be the most likely consumers of Western piece goods. Indeed, this hypothesis would agree with most nineteenth-century observations about who wore Western-style clothes. Though impressionistic, the documentary evidence is fairly clear that in Latin America, Turkey (Ottoman Empire), Southeast Asia and Japan, it was members of elite groups (e.g., the mestizos, the aristocrats, and the colonial indigenous leaders) who first dressed in Western fashions (e.g., Halperin-Donghi, 1973:85-90; Yanagida, 1957:9-30). Thus, one can suggest that Western textiles were initially luxury products whose comparative cheapness, when compared with other luxury fabrics, placed them within reach of other aspiring groups of individuals (e.g., merchants) who quickly emulated the dress of the socially higher ranked.⁷

If these qualifying remarks are accurate, then the fact that Chinese peasants did not buy Western piece goods because they lacked durability and were too expensive is also a fact among peasants in

many other non-Western societies. Thus, it does not explain why China consumed fewer Western fabrics than other countries. In fact, it complicates the question considerably because one must now explain why the richer members of Chinese society, whose attire differed greatly from that of peasants, did not consume Western fabrics.

(B) A possible explanation for why the more wealthy did not consume significant quantities of Western piece goods is that the traditional marketing system was simply too vast for Western goods to reach potential customers. Although one often finds this explanation in nineteenth-century sources (e.g., Cooke, 1858:202-6) as well as in modern studies, it contains some shortcomings when evaluated from a comparative perspective. Murphey (1974) and Feuerwerker (1969), among others, argue that in China an important factor in the lack of foreign trade was the inability of the Westerners to create a "modern" marketing system. Western commodities trickled into a fully-developed, well-supplied traditional economic system that was totally controlled by Chinese merchants. Western merchants were unable to obtain an adequate base from which to promote their products, so much so, says Feuerwerker (1969:57), that "foreign trading firms [were] gradually transformed into Shanghai and Hong Kong commission agents serving the established Chinese commercial networks."

The reasoning behind making the correlation between China's exceptionally efficient traditional marketing system and the limited Chinese demand for imported goods is ambiguous, at best. During the nineteenth century in most complex agrarian societies, non-Western commercial firms gradually replaced Western commission agents in handling textile imports. What happened in China is in no way exceptional. Simply put, Western merchants typically did not venture beyond the major trading centers to establish wholesale or retail outlets. Native firms, which had formed the link between the Western commercial houses and retail outlets, began to deal directly with the manufacturing firms. This change occurred

⁷ From this perspective, the textile handicraft industries supposedly ruined by Western capitalism were the ones that produced the more expensive fabrics consumed by the upper classes. This hypothesis also accords with such information as we possess. For instance, in South Asia the large textile handicraft industries which were hurt by Western competition were those that produced fine fabrics for the export and local elite markets (Chandra, 1968:52-62; Raychaudhuri, 1968:93-4; Halperin-Donghi, 1975:54). Too often this handicraft industry mistakenly is equated with the handicraft industries producing for peasant consumption, some of which survive today.

throughout the Ottoman Empire, Latin America, Russia, Africa and Southeast Asia (Platt, 1973; Skinner, 1958; Wickberg, 1965). Far from limiting the demand, the takeover by non-Western merchants intensified the distribution of Western cottons. Whether these developments in other non-Western societies mark the beginning of a "modern marketing system" or not begs the question.

For China, however, it is abundantly clear from the investigations of the Blackburn Commission that Western cotton fabrics and Indian cotton yarns were found throughout China, even in minor markets in the interior. Every other import that the Chinese showed they would consume (e.g., kerosene, cigarettes, matches) was likewise distributed throughout China. In fact, it should be argued that this vast and well-ordered traditional marketing system was better able to place Western imports in front of potential consumers than the marketing systems in most other non-Western societies, whether a "modern marketing system" or not. For the Westerners, the problem was that the Chinese simply would not accept much in the way of imports.

Nonetheless, the traditional economic system did have a direct effect in lowering the amount of imports sold in China. The reason, however, was not that it limited consumer demands but, rather, that it increased the supply of products first imported from the West. Those imports the Chinese did accept were constantly subjected to competition from native products produced in imitation of the imported item. Indigenous production of cigarettes, opium, matches, kerosene, factory-made cotton yarn, cotton piece goods, and even particular economic services (e.g., steamship transportation) rapidly gained a sizable portion of the market in competition with the respective import (Murphey, 1974; Feuerwerker, 1969; Morse, 1908:343-50; Liu, 1962: 151-6). The productive capacity of the Chinese economy certainly limited the *amount* of foreign commodities imported, but not the *range* of imports the Chinese would accept in the first place.

In summary, the faulty merchandise and marketing explanations attempt to ac-

count for the non-consumption of Western goods in terms of a universalistic consumer decision model: Economic man, rationally satisfying his needs, decides between competing items by weighing quality against cost—factors which, in turn, depend upon elements of production and distribution. When using this approach, one, of course, synthesizes a great deal of information about the Chinese use of Western imports. The approach, however, does not explain why the Chinese did not consume a wider range of Western products. What it does provide is a partial explanation for why the Chinese did not consume more of those items they found acceptable.

Perhaps one of the reasons for the limited explanatory value of this approach is because the question to be answered is essentially a comparative question: Why did the Chinese consume fewer and a smaller range of commodities than did people in other non-Western societies? In order to fashion a valid answer when using the universalistic consumer decision model, one must demonstrate that the economic factors influencing consumer decisions for the Chinese were *substantially different* from those factors in other societies. The faulty merchandise and marketing explanations do not demonstrate these crucial differences.

The Culture Explanations

Whereas the former explanations are based upon universalistic models, the culture explanation is based on a particularistic one. Explanations constructed from this model only apply to a specific culture—in this case, China. Of the three categories of explanations suggested in this paper, this category is the one most often used to account for the Chinese lack of interest in Western goods and, of the three, it is the most ambiguous.

The main tenets are easily described. China possessed a pervasive, well-articulated culture composed of a homogeneous set of institutionalized values emanating from the "Great Tradition" of Confucianism. Those who maintained this tradition were the upper class, educated and examined in its literature.

This upper class, the literati, indoctrinated other societal members in its prescriptions and set an exemplary standard for other groups to emulate. Because of the widespread geographical distribution of the literati and because this class (the literati) was not hereditarily determined, Confucian culture formed an especially powerful value-integrating orientation. In this role, Confucianism supposedly provided the principles through which Chinese society functioned.

There are typically two ways that this and similar characterizations of Chinese culture are used to explain China's non-consumption of Western imports. First, the literati were the model by which other Chinese judged appropriate behavior. Since it was in the interest of this group to consume the symbolic representations of Confucian culture, other social groups emulated their pecuniary canons of taste. Thus, this standard of consumption necessarily excluded Chinese interest in Western commodities. In this regard, Wright (1962) says, "In China, where imports of consumers goods were predominant, there are no signs that these imports reflected an undermining taste for foreign luxuries or any desire to ape foreign ways. . . . The Chinese upper classes, being non-Western, serenely preferred the tokens of their own culture." The second and closely related variant of the culture explanation suggests that because of the believed superiority of Chinese culture, Chinese were extremely ethnocentric, disliking all foreigners and, by default, foreign-made commodities.

The Blackburn Commission gives considerable indirect evidence that would seem to support this explanation. They recommended that Lancashire manufacturers not try to produce cloth for poor Chinese. Instead, because Western cottons were cheaper than silks and the better grades of handicraft cottons, a more appropriate market should be upper-class Chinese. They noted, however, that wealthy Chinese thought Western cottons to be inferior when compared with these native fabrics; if purchased at all, they were used to supplement, not to replace the more expensive native textiles. Decisive in this regard was the high status

associated with wearing silks: "Every individual [wears] silken fabrics if the nature of his work and his means enables him to do so" (Neville and Bell's Section, 1898:216). Thus, even though silk might sell at prices slightly higher than Western fabrics, its "consumer appeal" was much greater. The same sort of evaluation as that placed on silk also was placed on the best grades of handicraft cottons, especially those made entirely of Chinese cotton (Neville and Bell's Section, 1898:255).

More important, the Commission recommended that the Lancashire cotton manufacturers give the Chinese precisely what they wanted. The Chinese, they maintained, patronized commodities because they met Chinese cultural standards, not simply because they were Chinese-made. Hence, the Commission strongly advised that Chinese designs be accurately reproduced.

ornament applied to woven fabrics is in all cases symbolical to the Chinese mind. . . . A descriptive classification is attached to all products of the weaver's art by the Chinese themselves, and unless our manufacturers of cotton brocades pay attention to such minute detail they cannot hope to maintain their interests in these markets. . . . It is no use attempting to give a Chinaman a three-toed dragon instead of one with five, or vice versa; and it certainly is not a wise proceeding to irreligiously tamper with the traditional figure "motifs" of applied Chinese art. (Neville and Bell's Section, 1898:288)

The Commission even found that the Chinese dyed or in some way refinished an extremely large portion of imported cloth sold in China (80 to 90% of the English-made bleached shirting), with most of the remaining imports being used "for *under clothing*, or as *linings* to the various garments" (Neville and Bell's Section, 1898:289, emphasis added). Somewhat disheartened, they remarked, "It is not that these goods lack anything in bleach or finish—they are as perfect as good machinery and highly-developed skill can make them, it is that though [bleached shirtings] approach the Chinaman's requirements most nearly of anything we send him, yet they are not exactly what he wants" (Neville and Bell's Section, 1898:294).

The culture explanations are likewise appealing. They seem to account for why wealthier Chinese would not consume commodities symbolizing a non-Confucian way of life. The acceptable imports were thus those items which lacked cultural content (e.g., matches and cigarettes) or could be transformed into commodities having significance within Chinese culture (e.g., imported cotton yarn made into Chinese-style fabrics) or could be concealed (e.g., imported cotton cloth used as lining material). Yet, as acceptable as these explanations seem to be, they contain some ambiguities when examined from a comparative perspective.

The question is why should Chinese culture, at this point in time, *cause* more ethnocentrically-oriented patterns of behavior than did cultures in other non-Western societies? Was Chinese culture stronger or better articulated than were cultures elsewhere? The culture explanations are difficult to use in answering such questions because "culture" tends to be viewed as an indivisible whole. Inseparable aspects of the whole, such as the principles of propriety and filial piety, are considered unique to the particular cultural civilization. Thus, when comparing two cultures, one contrasts traits of two unique, holistic configurations. This makes systematic comparisons of similarities and differences impossible. Instead, what results from such comparisons is a tautological statement that people of particular societies do what they do because it is their cultural way to do so. In the case of Chinese culture, this problem of analysis is heightened by the belief that principles of Confucianism have had a continuous effect upon Chinese behavior for over two thousand years. In this role, Confucian culture becomes a "first cause," the unmoved mover of all that has happened in China. As Popper (1964) shows, for the purposes of analysis, such conceptualizations are useless because they cannot be falsified.

These objections notwithstanding, the culture explanations can be questioned on the basis of *intracultural contrasts*.⁸ For

well over the first thousand years of the imperial period, the Chinese regularly and widely consumed far more imports than they did during the last two dynastic periods, the Ming (A.D. 1368–1644) and the Ch'ing (A.D. 1644–1912). Moreover, most students of China consider the Han (202 B.C.–A.D. 220) and particularly the T'ang (A.D. 618–907) and Sung (A.D. 960–1279) dynasties to be high points in China's political, social and cultural achievements. The Ming and Ch'ing periods, however, are often viewed as a long period of decline in all these respects.

Because of several excellent studies, we know more about the consumption of foreign commodities during the T'ang than during the Han and Sung dynasties. In the T'ang period, quite unlike in the Ch'ing, the Chinese consumed an extensive variety of imports whose very acceptance depended upon their exotic appeal, their "foreignness." According to Schafer's (1963:28) study:

The Chinese taste for the exotic permeated every social class and every part of daily life: Iranian, Indian, and Turkish figures and decorations appeared on every kind of household object. The vogue for foreign clothes, foreign food, and foreign music was especially prevalent in the eighth century, but no part of the T'ang era was free from it.

The staples of foreign trade during the T'ang included many different kinds of foreign aromatics, drugs, woods, foods, and jewelry and a host of spectacular esoterica ranging from foreign birds and wild animals to slaves, musicians and dancers. Among the imports were foreign textiles and, more important for the purposes here, foreign clothing styles: "Fashions in the two capitals [of China] tended to follow Turkish and East Iranian modes of dress." Popular among men were such items as Turkish riding clothes, boots and "barbarian" hats and among women, veils, fitted blouses, pleated skirts, "long stoles draped around the neck and even

suggesting that the political, social and economic organization of the two periods were essentially the same. I am suggesting that culture explanations need to be specified. Whatever their shortcomings in this respect, temporal comparisons are a way to hold culture constant, thus aiding specification.

⁸ In the following temporal comparison, I am not

hair styles and makeup of 'un-Chinese' character" (Schafer, 1963:24).

The T'ang dynasty may be considered atypical by some because of the extensive influence of non-Confucian doctrines then promulgated by the imperial rulers. But during the Sung dynasties, at the height of both neo-Confucianism and literati authority, foreign trade was every bit as extensive as it was during the T'ang. In fact, the records of Chau Ju-kua (Hirth and Rockhill, 1970) and the fact that Southern Sung obtained twenty percent of the total imperial revenues from foreign trade alone (Ma, 1971) suggest that foreign imports may have increased between the two periods.⁹

Considering this striking contrast in the use of imports between the first half of the imperial period and the last half, the analyst faces a dilemma. If one uses the culture explanations to explain the lack of import consumption during the Ch'ing, then why should these explanations not also apply to the T'ang and Sung eras? Does one account for the difference by suggesting that the culture changed, hence allowing for the validity of these explanations for the Ch'ing? Or does one hypothesize that it is not Confucian culture but something else which determines the prevailing patterns of consumption, thus invalidating the culture explanations? This is not an enviable choice. To say that the content (i.e., the principal tenets) of Confucian culture changed flies in the face of evidence to the contrary. But to suggest that Confucian values did not influence Chinese consumer behavior seems equally untenable. A possible solution to this dilemma is to hypothesize that a change occurred in the way Confucian culture was maintained and interpreted within context of Chinese society. In other words, the structure of Chinese society changed between the two eras and not necessarily the content of Chinese culture. This hypothesis is the substance of the status competition explanation.

⁹ A short description of clothing styles during the late Sung period given by Gernet (1962:127-32) indicates some foreign influence on the style of dress, but certainly not as much as that which prevailed during the T'ang dynasty.

The Status Competition Explanation

The final explanation is one that emphasizes social structural parameters of consumption rather than economic or cultural factors. Although seldom encountered in the literature on the lack of Westernization in China, this explanation furnishes a basis for differential comparisons, which, in turn, provide an understanding of Chinese consumer logic.

The model upon which this explanation rests is straightforward. Insofar as they are able, individuals rationally purchase what they socially desire. Social desirability is a product of an ongoing situational process in which individuals choose the content and style of their consumption predicated on (1) what is available in that context and (2) how they view themselves in relation to their contemporaries. Thus, how a person decides on the social desirability of specific ideal and material goods is *in part* a function of his membership or aspirations of membership in what Weber (1968:937) calls a "status group": "Status groups are stratified according to the principle of their consumption of goods as represented by special styles of life." From this perspective, consumption is directly related to a person's social status and his efforts to substantiate that status by consuming "a style of life" in agreement with or in opposition to significant others. Hence, the content and style of consumption can be seen as a component of status competition, that is, competition in terms of ideal and material goods with significant others in the substantiation of one's status claims.

The task of analysis is to understand the composition and structuring of status groups in a particular context and to relate these two factors to an individual's consumption of goods. In this regard, Alexis de Tocqueville's distinction between aristocratic and democratic societies is useful. According to Tocqueville, (1969:530-3), distinctive styles of consumption prevail in aristocratic societies.

The rich in aristocratic societies, having never experienced a lot different from their own, have no fear of changing it; they can hardly imagine anything different. The comforts of life are by no means the aim of their

existence; they are just a way of living. They take them as part of existence and enjoy them without thinking about them. The . . . human taste for comfort being thus satisfied without trouble or anxiety, their faculties turn elsewhere and become involved in some grander and more difficult undertaking that inspires and engrosses them.

However, in democratic societies very different styles appear.

When distinctions of rank are blurred and privileges abolished, when patrimonies are divided up and education . . . spread, the poor conceive an eager desire to acquire comfort; and the rich think of the danger of losing it. A lot of middling fortunes are established. Their owners have enough physical enjoyments to get a taste for them, but not enough to content them. They never win them without effort or indulge in them without anxiety. . . . There is no question of building vast palaces, of conquering or excelling nature, or sucking the world dry to satisfy one man's greed. It is more a question of adding a few acres to one's fields, planting an orchard, enlarging a house, making life ever easier and more comfortable, keeping irritations away, and satisfying one's slightest needs without trouble and almost without expense. These are petty aims, but the soul cleaves to them; it dwells on them every day and in great detail; *in the end they shut out the rest of the world.* (Emphasis added)

I have quoted Tocqueville at length because I think here is a clue in understanding the problem I have posed. Nineteenth-century China was obviously not a democratic society, though nineteenth-century Western observers frequently referred to it as democratic (e.g., Cooke, 1858; MacGowan, 1889). Nonetheless, in this period, Chinese society has many of the structural characteristics of those societies that Tocqueville described as democratic. China did not have an hereditary elite but, rather, one whose members obtained formal and informal power positions through achieved means ranging from education to personal connections (Ho, 1964). Moreover, this elite was not a national elite. It was a local elite, locally determined through informal means and locally oriented in its exercise of power (Ch'u, 1969: 168-92). The nexus of this elite was

the locale—the standard marketing communities (Skinner, 1964; 1976), the district (Ch'u, 1969) or sub-district units (Freedman, 1965). Although there is some scholarly disagreement over the unit of the locale, it is agreed that the locale had a considerable political and economic autonomy from the bureaucratic state. In fact, Skinner (1976) insightfully argues that the influence of the locale in determining the organizational parameters of Chinese society extended to people of all income levels and was a principal factor in shaping "mobility strategies" by which individuals could aspire to artisan, merchant and official positions. These organizations (e.g., lineage associations, secret societies, *hui-kuan*) existing at the local level typically, but not necessarily, crosscut class lines so that one could find both the wealthiest and the poorest members of the local communities in the same organization.

Within this local society, an individual measured his success in relation to the success of others in his locale. Such a determination was always ambiguous because there was no rigid hierarchy of formal positions denoting the attainment of success other than office holding, which, by regulation, could only occur outside one's local community. However, the assessment of one's relative success was very important because the ability to exert influence in local affairs was strongly associated with one's social standing (Ch'u, 1969:175-7). Hence, status competition was a complex and very serious undertaking that interlinked those recognized to be successful, those claiming success, those aspiring to success and those clearly recognized to be unsuccessful. One of the best ways to demonstrate success or a claim of success was to practice a style of life that those along the continuum from the successful to the unsuccessful could agree revealed high social status. It is in this regard that Confucian culture is important because it contained those symbols of success—the accouterments of living the life of a gentleman—upon which all could agree.

In this context, as the status competition grew more intense, the symbols of status became more fixed and the local

inhabitants of all classes became more knowledgeable about the meaning of these symbols. In fact, one might hypothesize that the intensity of this competition helped promote the fad for domestic esoterica which was so prominent in the late imperial period but was less pronounced in earlier periods.¹⁰ These esoteric items (e.g., snuff bottles, carved miniatures of all varieties, silk textile designs) were certainly luxury goods, but those with a "middling fortune" could afford many of the items and those with greater wealth could obtain the most exquisitely made. This love of luxury did not go unnoticed by the Blackburn Commission: "The Chinese everywhere emphatically has [a taste for luxury]. He may be trusted to buy luxuries to the full extent of his means" (Bourne's Section, 1898:115). The Commission, however, saw this as an indication that the Chinese ought to be receptive to Western goods. As this analysis suggests, commodities having a Western symbolic content did not belong to those items which revealed a person's success.¹¹ Thus, to consume Western products was to put into question one's social standing, including one's influence in local affairs.

This line of analysis gains support from cross-cultural comparisons. In those complex agrarian societies accepting large quantities of Western goods (excluding such settler colonies as South Africa and New Zealand), one finds very similar

structural configurations. In each society, considerable social distance separated vertically-ranked status groups. The membership in these groups tended to be ethnically, religiously or hereditarily defined. For instance, in Russia a large number of Western products found ready acceptance simply because they were made in Europe, particularly France. However, the Francophilia that seized Russia was restricted to the Russian nobility and their retainers. Western commodities had a symbolic value precisely because the class lines were so sharply drawn. Holding a vastly superior rank in comparison with peasants, the Russian elite had been consciously cajoled into this pattern of consumption by the centralizing monarchs, especially Catherine the Great. Like France's Louis XIV, Russian rulers attempted to augment their power over Russian nobility by increasing the prestige of their status while at the same time reducing their political authority. They were turned into a cohesive leisured class with wealth but not responsibility (Von Laue, 1961).

South American elites likewise consumed Western products in large quantities but for slightly different reasons. In the revolutionary upsurge in the early nineteenth century, South American elites freed themselves from Spain's political domination. However, this elite group which had been formed during Spanish rule, was ethnically categorized as *mestizo*; that is, the members spoke Spanish, belonged to the Catholic Church, and generally adhered to Spanish patterns of behavior as these patterns were implanted in the New World. Like the Russian elite, they were socially cohesive and distinct from the rest of the indigenous population who were categorized as Indians. Even though they might have owned haciendas in the hinterland, the elites were cosmopolitan and the Indians rural. Unlike the Russian elite, however, the South American social elites also were the political leaders who maintained invidious distinctions as one of the means of maintaining their hegemony. During the nineteenth century, the consumption of Western commodities, especially from England, symbolically signified elite status, so

¹⁰ Connoisseurs of Chinese art often describe late Ch'ing art as being primarily composed of heavily stylized copies of the art of earlier dynasties. In contrast, T'ang and Sung art is seen as more free flowing and original, though lacking the technical perfection achieved in the Ch'ing period.

¹¹ This point is well illustrated by Chen's observations in the 1930s of the style of life adopted by Chinese returning to China after working abroad, and presumably exposed to Western styles, for many years. According to Chen (1940:111), successful returnees made an "effective display of pride" by showing "evidences of taste and culture. . . . [Their] ideal of 'complete happiness' . . . is not in fact anything new the emigrants bring back with them from abroad, but embodied in the folkways of the countryside. What they do contribute is financial ability to gratify these tastes. . . ." Watson (1975) makes identical observations in his excellent study of a contemporary single-lineage village in the New Territories of Hong Kong.

much so that the word *importado* became synonymous with quality and *nacional* synonymous with shoddy.¹²

In India, Western commodities were used by specific *jati* that in some way served the British, such as the Brahmin administrators and the Parsi merchants. In Thailand, which was never formally colonized, the Thai aristocracy westernized in the mid-nineteenth century after Chulalongkorn centralized his administration in response to Western pressure. In the Philippines, and to a certain extent in Malaysia, Western textiles became an increasingly important item of consumption among the upper classes.

Of all the places in Asia, however, the craze for Western commodities was especially prevalent in Meiji Japan where "The very word for 'imported article' was uttered with a feeling approaching reverence, and [the use of] foreign things was a source of great pride" (Yanagida, 1957:288). According to one Japanese account in 1878, "Although imported goods appeared only ten years ago, one sees them in the house and on the person of every member of the urban upper classes. People want anything foreign, whether it is of value or not" (Yanagida, 1957:289). The consumption of Western textile products ranged from hats and caps, the former being worn by the upper classes and the latter by soldiers and merchants (Shibusawa, 1958:31), to gloves and all the trappings of formal Western attire. Although some of these products later

spread to lower-class groups, the upper classes—the former aristocracy—were the first and the most frequent consumers of Western cloth and fashions, so much so that one analyst suggests that the use of Western clothing "simply emphasized the difference between the rich and the poor" (Shibusawa, 1958:25).

These and other examples strongly suggest that the consumption of Western commodities often reflected internal cleavages present in non-Western societies before Western industrialization began. And in each case, the elites of the respective societies consumed in a manner not influenced by subordinate status groups. In short, status competition was class-specific; for the elite, it was a competition among gentlemen.

These remarks also apply to the T'ang and Sung dynasties. During these periods, Chinese society was much more hierarchically structured than it was during the Ch'ing. T'ang society is noted for its hereditary aristocratic families, which supplied the court with officials and enforced sumptuary laws for other groups in the society. As Elvin (1973) shows, the social distance between the peasantry and the elite at this point in time was so great that it is analytically justifiable to refer to a "serf-like" peasantry. The cosmopolitanism of the T'ang and Sung dynasties was in large part a reflection of social elitism, a response of an upper class without roots in the peasantry.

Although the status competition explanation allows for the use of differential comparisons, the testing of the explanation, nonetheless, presents some difficulties. For instance, it can be argued, on one hand, that since Russia and Latin America are part of the Western cultural complex, the receptivity of their elites to factory-made commodities is not surprising. This line of reasoning is an application of a culture explanation. On the other hand, the status competition explanation, suggests that Russian and Latin American elites, having weak ties to local society, were more open to exogenous influences from whatever source. In this respect, Westernization in Latin America would be analogous to the vogue for Chinese products in eighteenth-century Europe, when

¹² The best summary of these patterns is found in Halperin-Donghi (1973:82-94). In regard to the use of Western textiles in Latin America, he (1973:86) writes, "From Mexico to Buenos Aires women began enthusiastically to accept the dictates of fashion which not only took for granted the acceptance of a new style, but above all that of periodically changing styles, which increased the consumption of imported cloth. The process was not restricted exclusively to the upper classes. In a society which ever since colonial times had been divided into only two sectors according to criteria which were not exclusively economic, any woman who did not wish to be associated with the lowest stratum had to use her ingenuity to follow the changing moods of fashion." An important point he makes, which also applies to Japan (Shibusawa, 1958:21-7), is the rapidity with which the people of these societies accepted Western clothing. In Mexico, the changeover occurred between 1824 and 1827 and in Japan between 1872 and 1884.

every manor house had its chinaware and other oriental luxuries. The demonstration that other aristocratic societies outside the Western cultural complex also welcomed Western commodities strengthens the status competition explanation, but this is not a definitive test. More research is obviously needed to refine the comparative testing of these explanations—perhaps by looking for elites who retained their native dress (as did the tribal leaders of West Africa and the Persian Gulf) or by finding variation in Westernization within societies that generally consumed Western products (as occurred in portions of Southern Mexico where elites, having strong affiliations within Indian communities, continued to dress as Indians).

Despite the difficulties in comparative testing of alternative explanations for a particular occurrence, there are few other approaches as useful in isolating possible causal relationships and in weighing the contribution of each explanation. As this case study has shown, each alternative has some merit, even though none of them alone is able to account for the non-consumption of Western goods in China. But together they form a composite answer to this question. The faulty merchandise and marketing explanations allow insight into a dynamic traditional economy that was able to produce effectively many Western commodities the Chinese found acceptable. That the Chinese did not import more of those acceptable items is explained, in part, by these explanations. The status competition explanation suggests some parameters of the situational logic by which individuals evaluated a range of possible consumer choices in relation to their relative social standing within the community. That the Chinese did not find exogenous commodities acceptable symbols of status is best interpreted by means of this explanation. The culture explanations provide an understanding of those commodities that did reflect one's success or claims of success.

Conclusion

If one narrowly defines "Westernization" as the adoption of Western styles

and the purchase of Western commodities—thus analytically distinguishing this process from other processual aspects of Western expansion (e.g., political modernization, industrialization)—then some generalizations can be tentatively offered. The above discussion suggests that Westernization would be more likely to occur in those non-Western societies in which there are established elite status groups. If these elite status groups also effectively controlled political power within their respective societies, as they did in Latin America, to a certain extent in Japan and to a lesser extent in Russia, then one might further argue that Westernization can be regarded as an *indicator* of the maintenance of a pre-modern political and social structure. Thus, it is not unreasonable to alter Marx's prediction, quoted at the beginning of this paper, to say that the purchase of Western commodities reproduces the old world in new dress.

This conclusion is, of course, in agreement with some recent efforts to show that contemporary Japanese and Latin American societies exhibit considerable continuity with the pre-modern period. However, in contrast to some of these efforts, the important point to be made here is that Westernization should not be viewed as necessarily antagonistic to the preservation of the old order, with historical continuity being maintained in spite of it. Rather, in such highly stratified societies, Westernization might be better viewed as a new way to signify, as an attempt to reaffirm, a traditional social order.¹³

The relative lack of Westernization in China, given its very different system of stratification, reveals substantially the same outcome as that experienced in most other societies, namely, the choice not to break decisively with the past. Thus in theory, at least, China should not be seen as a negative case in terms of its rejection

¹³ This hypothesis implies a slight but significant alteration in the posited (e.g., Frank, 1967) direct relationship between Western capitalism and underdevelopment in the third world. The implication here is that the relationship is not direct but, rather, is mediated through political and stratificational systems, in which variance would produce different outcomes at different times and places.

of Western influence simply because the Chinese failed to patronize the products of Western factories. The spread of Western civilization, even in an economic sense, is more complex and subtle than this. And Westernization, though significant and interesting, is hardly the whole story. In fact, it could and perhaps should be argued that the Chinese responded to Western economic expansion in more aggressive and positive ways than did individuals in many other non-Western societies. For instance, the Chinese, more than any other group of non-Westerners, became the principal retailers of Western products and exporters of raw products to the West throughout all of Southeast Asia and portions of the Pacific and the Caribbean. To call this collective action of millions "unresponsive to Western influence" is certainly dubious.

Therefore, if these suggestions have some validity, then the expansion of Western civilization is by no means an unambiguous process. Its analysis requires more than that which an economic, political or sociological perspective can alone provide. But, in combining these perspectives, one must strive for an analytic framework that facilitates the use of differential comparisons, for only by making systematic contrasts can one begin to disentangle the complexity of civilizational encounters.

NUMBERS GAMBLING AMONG BLACKS: A FINANCIAL INSTITUTION*

IVAN LIGHT

University of California, Los Angeles

American Sociological Review 1977, Vol. 42 (December):892-904

Mainstream financial institutions have never been able to provide generally prevailing service levels in poor communities. In the resulting partial-service vacuum, blacks invented numbers gambling. Numbers-gambling banks became sources of capital and a major savings device of urban black communities. In conjunction with the usury industry, numbers banks framed an alternative institutional system for the savings-investment cycle in the slum. Numbers banking illustrates the conjoint contribution of institutional and cultural causes in analysis of poverty.

CULTURAL AND INSTITUTIONAL EXPLANATIONS OF POVERTY

The literature on poverty conventionally distinguishes institutional and cultural explanations (Light and Wong, 1975; Elesh, 1977). The distinction hangs upon whether an explanation identifies social institutions or the culturally-induced behavior of the poor as the cause of poverty. Although this taxonomy satisfactorily encompasses the structures of explanation, two intervening processes always precipitate poverty. These two are low income and wasteful and/or destructive consumption.

Low income is the most obvious cause of poverty, but the balance between income and consumption is always the technical issue. Even where disposable family incomes are above the poverty level, wasteful or destructive expenditures may deplete a family's reserve until income is no longer adequate. In this case, wasteful consumption—not low income—actually caused a family's poverty. Naturally, when incomes are inadequate, low income becomes the immediate cause of poverty but, even here, wasteful or destructive consumption can exacerbate it.

The intervening processes of low income and wasteful/destructive consumption are compatible in principle with either institutional or cultural explanations of poverty. For example, institutional explanations of income-induced poverty have stressed external barriers imposed by racial discrimination, structural unemployment, minimum wage laws, labor exploitation, the split labor market, and so forth. Cultural explanations of low income-induced poverty have stressed unfavorable work habits (absenteeism, soldiering, tardiness) which reduced employability, attributing these variously to the lack of a Protestant ethic, or the presence of employment and earning-inhibiting cultural residues (Banfield, 1974).

On the neglected consumption side, cultural explanations have emphasized the adverse consequences of wasteful/destructive consumption habits allegedly characteristic of the "disreputable poor" (Matza, 1966). For example, in the decades of temperance agitation preceding the Prohibition Era in the United States, much social research concerned insobriety among the working class and the putative connection of drinking and pauperism (Koren, 1899: 64-99). Many other consumption habits have been linked to poverty, among them: unsophisticated shopping, purchase of luxuries, big families, unhealthy diet, excessive use of installment purchase, failure to save and gambling (Glazer and Moynihan, 1970: 33; Foxall, 1974).

* The author gratefully acknowledges a grant from the University of California Academic Senate, Los Angeles Division. The American Bankers Association permitted inspection and reproduction of their unpublished research findings. The author also wishes to thank Oscar Grusky, Robert Herman, Joan Huber and Lynne Zucker for advice.

One institutional response to this catalogue of wasteful consumption practices has been to question the scope of culturally-induced consumption differences between the poor and nonpoor. This issue produced a complex and contradictory literature which permits no easy encapsulation (Alexis, 1962; Nixon, 1963; Simon and Simon, 1968; Stafford et al., 1968; Sturdivant, 1969; Cicarelli, 1974). In some cases, undeniable income-linked differences have appeared—for example, lower rates of life insurance purchase by the poor. Even here, institutional writers have insisted that poverty produces situational pressures which require the poor to seek irregular and often more expensive alternatives to those prevailing elsewhere in the market (Light, 1972: 152–69; Ferman and Ferman, 1973; Wong, 1977). In a memorable phrase, Caplovitz (1963) observed that “the poor pay more” because the retail stores of the slum compel it. Similarly, successive studies of pawnbrokers and loan sharks have concluded that poor people turn to high-priced lenders because they are unable to obtain credit in cheaper institutions (Forman, 1906: 622; Seidl, 1968: 88–9). In all of these cases, the poor are making unwise, destructive or wasteful purchases, but circumstances rather than improvidence necessitates the waste.

The ideological implications of any simply cultural or simply institutional explanation of poverty are mutually repugnant (see Huber, 1974), and a spirit of dogmatism often has characterized social science discussion as a result. The source of this dogmatism is the insistence that cultural and institutional theories of poverty must exclude one another. This insistence is fallacious because cultural and institutional explanations can produce poverty jointly as well as singly. Recognizing this possibility of conjoint causality, Valentine (1968: 117) nonetheless condemned it as “eclectic,” and social scientists have been dismayingly willing to accept this unwarranted constraint.

The treatment of Lewis' (1968) “culture of poverty” thesis is a case in point. Lewis' detractors as well as his defenders accepted the premise that his thesis is a cultural theory (Leacock, 1971). Yet, the

premise is strictly untrue for, in Lewis' view, historic institutions gave rise to contemporary cultures of poverty. His total explanation actually included both institutional and cultural components so it was never a purely institutional nor a purely cultural explanation. The controversial Moynihan report was only a specific application of Lewis' formula to American blacks (Rainwater, 1967). Moynihan asserted that slavery, a bygone institution, had engendered a matriarchal cultural tradition among blacks. The female-headed family, a cultural survival of the bygone institution, had become the principal cause of poverty among American blacks today. Moynihan's thesis contained cultural and institutional components; it was never a purely cultural explanation.

True, a purely cultural phase succeeded a purely institutional phase in both the Lewis and Moynihan versions. (The sequence might, in principle, have been reversed.) On the other hand, no barrier prevents institutional-income and/or institutional-consumption causes from coexisting in time with cultural-income and/or cultural-consumption causes. Numbers gambling offers empirical confirmation of this logical possibility. Numbers gambling is a wasteful consumption practice of the poor. Existing literature attributes this wasteful consumption to cultural causes. This cultural-consumption orthodoxy is simplistic. Actually, numbers gambling combines institutional and cultural causes in the same time span. Therefore, this empirical case supports the conclusion that institutional and cultural causes of poverty may operate conjointly in a situation, and that empirical determination of preponderance is necessary in every case.

NUMBERS GAMBLING: A FINANCIAL INSTITUTION

In the late nineteenth century and until roughly 1940, policy wheels were the prevailing type of lottery among urban blacks and whites of the lower class. Although policy gambling persisted in Chicago and Detroit until 1940, numbers gambling by now has replaced policy in all major American cities. In numbers gambling, a

"gig" bettor stakes a small sum on three digits, 000 to 999. Instead of a wheel or drum, the house takes its winning number from published numbers such as bank clearing totals, volume on the New York Stock Exchange, or parimutuel totals. The published figures eliminate the possibility of a rigged outcome, a decisive technical advantage over the policy format (Light, 1974). Beale and Goldman (1974: 541; cf. Roebuck, 1967: 136; *Black Enterprise*, 1973: 12) estimate that numbers gamblers in the United States wagered 2.5 billion dollars in 1973, roughly ten percent of all illegal gambling revenue.

Discursive evidence claims that blacks were overrepresented among policy gamblers, but the implications of these statements are unclear (Crapsey, 1872: 104; Martin, 1868: 517; Du Bois, 1899: 265). There is no evidence that blacks were overrepresented relative to poor nonblacks; in addition, white ethnics commonly had their own lotteries which may have been functional equivalents of policy gambling (Ianni, 1972: 67; Carlson, 1940: 24). However, Caribbean blacks invented and popularized numbers in this country during the 1920s. As a result, numbers gambling was still 60 percent black in 1934 (Light, 1974: 55). Carlson (1940: 3-4; see also Caldwell, 1940:2) noted that although "white people of the lower economic classes" had begun to bet on numbers, this form of gambling remained "predominantly an urban negro [sic] activity." Currently, Marcum and Rowen (1974: 31) observe that numbers gambling is "concentrated among blacks and ethnic groups in the older cities, especially in the East and Midwest." The Fund for the City of New York (1972) found that blacks represented 30 percent of numbers bettors, but only 20 percent of the city's population. This progression indicates that numbers began as an exclusively black lottery, but diffused to nonblacks.

Studies of lottery gambling, even those most sympathetic to blacks, have always regarded the betting as superstitious nonsense justifying a prodigal waste of money (Riis, 1892: 155; Peterson, 1952: 194; Drake and Cayton, 1962: II, 491). The amount wasted is substantial. Drake and

Cayton (1962: II, 481; cf. Warner and Junker, 1941: 19) concluded that the policy syndicate on Chicago's South Side employed 5,000 persons and grossed at least 18 million dollars in 1938. This sum would represent \$64 for every black person in Chicago and \$256 for a family of four. The median income of all families in Chicago was \$1,463 in 1940, so numbers gambling of blacks accounted for about 17.5 percent of family income. More recently, the Fund for the City of New York (1972: 9) concluded that New Yorkers wagered 600 million dollars a year on numbers bets. Blacks represented 30 percent of New York's numbers bettors, so the city's black population presumably laid 180 million dollars on numbers in that year. This sum represents \$87 for every black person in New York City. Since the median family income of blacks in New York was \$7,309 in 1969, nearly five percent of black family income went for numbers gambling. This estimate is conservative. Director of Political Affairs for the Congress of Racial Equality, Ed Brown (1973) has claimed that in Harlem alone blacks wager "at least" 300 to 500 million dollars a year on numbers. If only 300 million dollars were wagered yearly, this betting gross would represent about \$300 for every black person in Harlem or 16 percent of family income. In the 94 percent black Bedford-Stuyvesant section of Brooklyn, Lasswell and McKenna (1972: 55-62) examined numbers gambling between 1963 and 1970. Their estimates are the most reliable of any. They found that impoverished residents spent between 2.5 and 5.1 percent of per capita income on numbers bets. Admittedly, these estimates of betting volume are crude and vary widely. Nonetheless, even the lower estimates indicate that numbers betting represents a significant waste of money by poor people.

Why do poor blacks waste money on numbers? The sociological literature on gambling is scanty (Scimecca, 1971: 56; Tec, 1964: 105) and it offers only two efforts to explain numbers gambling as opposed to gambling in general, the usual focus. The two offer exclusively cultural explanations. Carlson (1940) called attention to "the culture complex" underlying

the numbers gambling of Detroit blacks. This complex included dream interpretation, folklore, and music, social roles, spiritualism, ceremonial festivities, fad and fashion in playing style, and an extensive gambling jargon. McCall (1963) stressed the "sympiotic" relationship between spiritualist cults and numbers gambling, claiming that the superstitions mutually reinforced each other. The cultural source of the superstition McCall identified as animistic religions of West Africa and Caribbean "hoodoo." In view of the heavy folklore surrounding the numbers complex, cultural explanations have an undeniable plausibility. Moreover, the metropolitan black press continues to depict numbers gambling as a "soul" preoccupation (E. Brown, 1973) while reminding readers that blacks invented the game. In all cases, what is evoked is a specifically black cultural heritage rather than a generalized "culture of poverty." Nonetheless, the prevailing cultural interpretation of numbers gambling among blacks comes down to a cultural-consumption interpretation of poverty among this group.

The evidence supporting the cultural side of black numbers gambling is too strong to deny, but a close look at numbers gambling turns up three telling anomalies. First, of cultural theories of gambling in general, the preeminent is Devereaux (1968; see also Thurner, 1956) who stresses the incompatibility between gambling and the Protestant work ethic. The obvious difficulty is that black numbers gamblers are predominantly Protestant fundamentalists whose gambling can only occur despite the restraint of this religious tradition. Hence, the cultural baggage of blacks does not provide un-mixed support for numbers gambling. Second, a cultural explanation of black numbers gambling cannot account for the 70-80 percent of numbers gamblers who are now nonblack. This objection was less serious when numbers was an exclusively black preoccupation, but the subsequent diffusion of the game to nonblacks compels the conclusion that cultural continuities originating in the black heritage cannot give the whole explanation. The supposed improvidence of the lower class

offers a class cultural explanation for numbers gambling by the black and nonblack poor. However, the actual distribution of gambling among social classes lends little evidentiary support. Li and Smith (1976) reported national survey data which show that the propensity to gamble is positively associated with socioeconomic status, a result repugnant to any class cultural theory. The best evidence cited in support of a negative relationship between socioeconomic status and gambling is Tec (1964; see also Newman, 1972: 85). However, Tec concentrated only on football pool gambling, an admitted preoccupation of the working class. Numerous studies (Bloch, 1951: 218; Commission, 1975: 13) report that identifiable social groups have favorite gambling activities. For example, the Fund for the City of New York (1972) reported that low-income gamblers preferred numbers, but high-income gamblers preferred casino games; at middle-income levels, sports and race track betting prevailed. This mosaic of gambling preferences implies that the correlation between socioeconomic status and gambling depends upon which gambling game is under scrutiny.

Third, a fundamental assumption of any cultural theory of gambling is the expectation that rates should remain stable over long periods of time in reflection of cultural divergences. But the history of lottery gambling in general (Light, 1974: 52-3) and numbers gambling in particular (Carlson, 1940: 4, 138, 158; Caldwell, 1940: 30) shows abrupt shifts in participation: lottery gambling increases in frequency in economic hard times and declines in periods of prosperity. Cultural theory cannot account for cyclical fluctuation.

On the other hand, the increase in numbers gambling in periods of business depression immediately suggests the anomie theory (Durkheim, 1951: 241-46). Merton (1957: 149) also identifies the numbers gambling of blacks as a form of "innovative deviance." Big prize lotteries offer the possibility of immense wealth to winners, and sociological treatments of these have commonly asserted that working-class bettors hope to strike it rich (Stock-

ing, 1932: 558; Marcum and Rowen, 1974: 30; Ianni, 1974: 110), a conclusion congenial to anomie theory (Tec, 1964: 62; Zetterberg, 1962: 122). A related view has developed in economics since the analysis of Friedman and Savage (1948) reversed the economists' long-standing belief that gambling is always irrational. Even the enemies of gambling within the economics profession now acknowledge that gambling is "rational when a person's wish to obtain an otherwise unattainable large prize is very large" (Rubner, 1966: 52). Eadington (1972: 24; see also Off Track Betting Corporation, 1973: II) assumes that numbers gambling satisfies this condition and, thus, justifies its economic rationality.

Anomie theory fits big prize lotteries, but it does not fit numbers gambling because numbers bettors do not expect to change life-style when they win. On an average bet of one dollar, a numbers winner receives a pot which may range from \$500 to \$600. Players are expected to tip the runner ten percent of winnings, a practice which reduces net gain to \$450-\$540. In the depressed Bedford-Stuyvesant sector of Brooklyn, slum dwellers averaged only 50 cents a numbers wager, so their expected return was only \$225 to \$270 in 1970. These calculations exaggerate expected return because the game permits less radical bets than the three-digit gig. In "single action," for example, a bettor selects only one digit at odds of 10 to 1. The maximum return in this popular bet is only \$6, less the runner's tip. These returns fall far short of riches permitting a change in life-style.

Personal Saving

Sellin (1963:19; see also Ianni, 1974: 110) supposes that numbers gambling thrives because a "segment of the population enjoys betting" and does not regard it as harmful. But the entertainment theory does not correspond with the bettors' understanding of the numbers game. On the contrary, they vigorously disclaim betting for the thrill, fun or sport of it. Numbers gamblers view the game as a rational economic activity and characteristically

refer to their numbers bets as "investments" (Carlson, 1940: 138-9).

Most gamblers understand their numbers betting as a means of personal saving. This ubiquitous self-justification is the crucial prop for the entire gambling order (Eadington, 1972: 29; Ianni, 1974: 78). The bettor's justification for this seemingly preposterous misconception arises from unsatisfactory experiences with depositary savings techniques. Once a numbers collector has a man's quarter, they aver, there is no getting it back in a moment of weakness. If, on the other hand, the quarter were stashed at home, a saver would have to live with the continuing clamor of unmet needs. In a moment of weakness, he might spend the quarter. Therefore, in the bettor's view, the most providential employment of small change is to bet it on a number (Grow, 1939: 213; see also Whyte, 1943: 41). "The dime or quarter which one bets is scarcely missed," writes R. Brown (1973), "but when one 'hits' the payoff is a chunk of money large enough to be really useful to the winner." Bettors do win (Johnson, 1971: 42). On an average day, the betting public receives back in "hits" fifty percent of its total wager. From the bettors' perspective, numbers gambling is a means of converting change into lump sums; in effect, a savings method (see Samuelson, 1973: 423; Commission, 1975: 17).

The methodical style of numbers gambling also indicates that bettors have adopted a long-range perspective, suggesting a rational savings strategy. The Fund for the City of New York (1972: Appendix 15) found that 72 percent of numbers bettors placed a bet "two or three times a week" and 42 percent bet every day. The Off Track Betting Corporation (1973) concluded that: "The typical numbers player currently wagers on the game between 2 and 4 times a week." Even more strikingly, the Fund for the City of New York (1972: Appendix 25) found that 41 percent of numbers bettors had been betting on the game for ten years or more, and 59 percent for six to ten years. Indeed, the largest bettors were those who had been playing the longest. The frequency of wagering and the decades-long perseverance of numbers gamblers outlines an average

playing career which encompasses 1,300 trials. In a decade of gambling at this rate, a gambler confidently can expect to hit at least once (for \$550) against his total investment of \$1,300. Viewed from a decade's perspective, the expected return of a numbers gambling career approaches the expected value of the game (Ignatin and Smith, 1976; Ianni, 1974: 78; Eadington, 1972: 205).

Numbers games attract funds which would not otherwise be saved in depository accounts (cf. Rubner, 1966: 36). First, numbers gambling is convenient. Numbers runners make a regular circuit of their customers who thus do not have to go out of their way to bet. In addition, numbers stations are located in newsstands, pool halls, cigar stores and groceries which people visit on an average day. Therefore, even people who have savings accounts find it convenient to lay a dollar on a number while at the barber shop rather than risk making no "investment" at all in the day. The fund for the City of New York (1972: 57; see also Haller, 1970: 623) concluded that a legalized numbers game would require seven to ten thousand outlets to compete with the illegal game in convenience. In 1970, Bedford-Stuyvesant alone contained 1,345 numbers runners whose business was making it easy to bet (Lasswell and McKenna, 1972: 111).

The friendly atmosphere of numbers gambling encourages "saving." People choose to deal with a numbers runner whom they trust and like (McKay, 1940: 112-3). Therefore, interactions with this person are enjoyable. An established numbers station is usually operated in a small grocery store, candy shop or beauty parlor. Stores of this sort often serve as neighborhood hangouts as well as retail outlets (cf. Whyte, 1943: 143; Firey, 1947: 190). When placing a bet, a gambler has an opportunity for a few moments of sociable interaction with whomever is hanging around. The sociable atmosphere of a numbers station thus stimulates to "saving" these persons who would otherwise simply have spent all small change.

Numbers gambling also appeals to the race pride and community spirit of the ghetto public. The real extent of altruistic

motivations is unclear, but the experience of state lotteries suggests that altruistic motives do induce some people to gamble. When asked why they purchased Connecticut state lottery tickets, 82 percent of bettors mentioned financial reasons and 33 percent the benefit to the state.¹ In some cases, blacks have actually gotten together in order to set up an unemployed friend as their numbers runner (McKay, 1940: 112-3). However, even in cases where the direct support of a friend is not involved, blacks understand their numbers gambling as a local form of work-relief (Drake and Cayton, 1962: II, 493; Ottley, 1943: 155; Black Enterprise, 1973: 44; Ofari, 1970: 44-5). Numbers gambling syndicates do provide a lot of employment in black communities. Lasswell and McKenna (1972: 168) found that numbers gambling syndicates were the largest employers in the slum, second only to the federal government. Numbers collectors frequently double as town criers and fund raisers on their rounds. One black informant, an experienced collector in Detroit, observes that passing the hat for hard-luck cases was a regular function of his daily rounds. In this manner, the people who regularly dealt with him put themselves into a loose federation for mutual assistance in time of need.

Consumer Credit

In addition to drawing savings out of an impoverished population which finds saving difficult, numbers-gambling banks also make credit available to poor people who would otherwise be unable to obtain it (Dominguez, 1976: 38). The capital fund from which this credit derives is the gambling play of the neighborhood. The methods by which this capital returns as credit to the local economy are sometimes circuitous and sometimes direct.

Numbers runners make direct loans to customers. These direct loans are of two sorts. First, numbers runners sometimes permit the needy to borrow the where-

¹ I am grateful to John T. Macdonald and Fillis W. Stober, State of Connecticut, Commission on Special Revenue, for showing me these unpublished tabulations.

withal to bet. Eighteen percent of numbers players in New York City acknowledged placing bets on credit (Fund for the City of New York, 1972: Appendix 29). Among those who bet a dollar or more per day, this percentage increased to 23. Second, some runners lend cash to steady customers. Nine percent of numbers players in New York City had borrowed cash from their numbers runner for some purpose other than betting. Among persons who usually bet a dollar or more per day, this percentage increased to 15 percent. These percentages are modest, and there is no indication of how recourse to credit varies with income or color. On the other hand, a 1970 sample of California households (Day and Brandt, 1972: Table 6.2) found that eight percent of white and 15 percent of minority households with annual incomes less than \$7,500 reported borrowing money from a credit union. Therefore, the direct credit service of numbers gamblers is roughly comparable to credit unions in a low income population.

A wider credit conduit is the return to the local community of numbers gambling profits as loan shark's capital. This return is the standard underworld employment of numbers gambling profits (Seidl, 1968: 32-3; Kaplan and Matteis, 1968). Consumers and small businessmen are the principal customers of slum loan sharks who actually frequent banks in order to approach disappointed loan applicants, sometimes being waved or pointed out to these by the platform official (Seidl, 1968: 16-7; 109-19, 139; Congressional Record, 1967). In many cases, numbers gamblers and loan sharks are the same individual, who simply transfers money from one pocket to another when he changes roles (Anderson, 1974: 25, 127, 130-1; Ianni, 1974: 80, 136; Knudten, 1970: 140).

Business Investment

Numbers racketeers have been the largest investors in black-owned business or ghetto real estate and the chief source of business capital in the ghetto (Roebuck, 1967: 142; Drake and Cayton, 1962: II, 487; Caldwell, 1940: 153; Strong, 1940: 133; see also Whyte, 1943: 145; cf. Ofari, 1970: 46). In addition, numbers bankers

have been virtually the only sources of business capitalization available to local blacks lacking collateral or credit rating (Cook, 1971). As a result of these loans, black-owned businesses not actually owned by numbers bankers were often in debt to them (Drake and Cayton, 1962: II, 469). Finally, numbers bankers have been leading philanthropists in depressed black neighborhoods, making donations to churches and athletic teams, and providing Christmas and Easter baskets for the poor (cf. Perucci, 1969; Whyte, 1943: 142-5).

MAINSTREAM FINANCIAL INSTITUTIONS: MALFUNCTION

One way to appraise the importance of numbers gambling in the financial life of the slum is to compare this subterranean financial system with the saving and investment services of mainstream financial institutions, such as banks. Even a casual review of relevant literature proves that mainstream institutions do not now, nor have they ever in the past (U.S. Immigration Commission, 1911: 216) been able to provide the same standard of financial service in depressed communities which they routinely provide in affluent ones (Hiltz, 1971; Dominguez, 1976: 18). The chronic malfunction of mainstream financial institutions in the slum leaves an enormous service gap in which a diversity of popular financial institutions—including the numbers racket—plausibly may flourish.

Saving

Poor people in general and nonwhites in particular make less use of banks for savings or checking accounts than do non-poor (Lewis, 1968: 190-2; Irons, 1971: 420). Low income is the most obvious cause: the less money people earn, the less they have to deposit in banks. National survey data confirm this expectation (see Table 1). The consumption of banking services declines as income declines. Of those who own no savings account, 75 percent (1972) and 80 percent (1970) explained that lack of "money left over" after paying bills was the reason

Table 1. Usage of Banking Services by Color and Family Income, 1966 and 1972

	Have a Savings Account (%)		Have a Regular Checking Account (%)

* Regular and/or special checking account.

(Harris, 1972: 73; Opinion Research, 1966: 39). Among those who had no checking account, 45 percent (1962) and 46 percent (1966) blamed lack of money, the modal explanation.

Investment

A result of nondepositing in banks is noncreation of capital funds in them. This shortage begins the "capital gap" in the inner city, a condition which strangles consumer, mortgage and business credit alike (Garvin, 1971: 445). Moreover, such funds as do make their way into deposit accounts in low-income areas do not, in general, find local investment outlets. Because they lack collateral and have irregular and low income, poor residents make bad risks for bank loans (King, 1929: 18-9; Neifeld, 1939: 169; Dominguez, 1976: 19). In addition, the sums poor people borrow are normally too small to permit profitable lending (U.S. Senate, 1970: 89, 160; 1968: 404). Even credit unions require federal subsidies to offer loans to the poor at legally permissible rates of interest (Cargill, 1973). Therefore, consumer finance companies, like banks, also avoid poor families (Booth, 1973: 71).

Small business loans in poverty areas are more risky than investments in corporate or government securities (Cross, 1969: 45, 46; U.S. Senate, 1970: 148). Adverse profit considerations also have shaped mortgage lending policies in inner cities. Savings and loan associations

routinely refuse to issue mortgages in "red-lined" areas deemed to be in deterioration (U.S. Senate, 1975). The undesirability of consumer, business or mortgage investment opportunities has resulted in a flight of capital from the inner city to more profitable suburban locations (see Orren, 1974: 145-78). A source of interracial tension, this flight of capital owes more to economic calculation than to color prejudice. In 1971, for example, all U.S. banks had 13 percent of total assets in government securities whereas the nation's 20 black-owned banks had 30 percent of their assets so invested. The ultra-conservative investment policies of the black-owned banks led Brimmer (1971) to observe that the black banks were "diverting resources from the black community into the financing of the national debt." This investment policy contributes to the "almost total void of low cost credit and capital" in the inner city (U.S. Senate, 1968: 408).

Bank-Community Relations

Nonfinancial barriers to the normal operation of depository institutions arise from the mutual lack of sympathy of bankers and the poor. The cultural ethos of a bourgeois society provides bankers with no basis for an indulgent view of poor people, and the problem is more acute when the poor are also nonwhite. Blacks have complained for over 200 years that

white bankers discriminate against them (Light, 1972: 19). This persistent complaint turned up in Harris' (1972: 94) research for the banking industry. In this survey, 43 percent of nonwhites but only 18 percent of whites agreed that banks made it "too difficult" for nonwhites to obtain loans.

Banking industry research (Harris, 1970: 97-8) confirms that the loan turnaround rate "has been highest among lower income groups and nonwhites." Bankers also have acknowledged the interpersonal problems which arise when white credit managers refuse nonwhite customers (U.S. Senate, 1970: 195-6). However, banking industry spokesmen have denied that bankers' race prejudices were the source of the problem (Haugen, 1968: 103; U.S. Senate, 1970: 160; see also Marsh, 1971). The practical line between prejudice and an adverse but impartial bank decision is difficult to draw because of the connection of color characteristics with economic marginality. A U.S. Senate (1968) investigation addressed allegations that the racism of white bankers was responsible for the inner-city financial gap. However, the extensive hearings provided no evidence of more than a clash of cultural standards; and subsequent research also has unearthed no evidence that the color antipathies of bankers distort their business judgment.

Nonetheless, poor minorities fervently believe that bankers discriminate against them and discourage their patronage (Day and Brandt, 1972: 102). This belief nourishes the antipathy of these people to banks (Cross, 1969: 51, 54, 66; Kurtz, 1973: 55). Banking industry research shows a decline of confidence in banks as family income declines (Harris, 1972: 28; 1970: 46), but color makes an autonomous contribution. Black people are more alienated from banks than would be expected on the basis of income or educational attainment alone (Root, 1966: 65). Selby and Lindley (1973) found that Atlanta blacks were less prone than whites to maintain a checking account, even holding constant the blacks' generally lower income and educational level. Similarly, banking industry research (Harris, 1972: 49) found that among families

with incomes under \$6,000 a year, the poorest class, 62 percent had checking accounts but only 48 percent of nonwhites did (Table 1). More generally, surveys record a level of disenchantment with business and banks which is higher among nonwhites than among the poor. For example, Harris (1972: 131) found that among families with annual incomes less than \$6,000, 37 percent rated banks "very high" in their concern for helping the local community, but only 28 percent of nonwhites agreed. Harris (1970: 130) also found that among families with annual incomes less than \$6,000, 34 percent perceived bankers as "highly concerned" with helping their community, but only 16 percent of nonwhites made this friendly rating.

Naturally, many expressions of mistrust reflect hostile stereotypes rather than harsh experience. Harris (1970: 46; also Hiltz, 1971: 996) reported that nonwhites indicated less familiarity than whites with every type of financial institution except the sales finance company. Ignorance and public image in principle are open to change through "education" which bankers now view as the key to extending their market in black and low-income areas. The banks' record of recent extensions in response to "advertising and promotional activities" proves that poor people's unfavorable attitudes are open to suasion (Opinion Research, 1966: 74).

However, the malfunction of mainstream service in inner cities is neither epiphenomenal, nor easily rectified within a profit system. To extend service markets in low-income neighborhoods, depository institutions must surmount the barriers posed by the residents' poverty as well as their ignorance of and antipathy toward banks. Although the record of recent extensions proves these barriers are not insuperable, the dollar costs of attracting new bank customers increase as the income of the new customers decreases, but marginal revenues decline. Hence, profit-making institutions cannot provide normal service levels in poverty areas. As a result, the private burden of supporting the savings-investment cycle in such localities falls upon whatever financial institutions the poor improvise.

CONCLUSIONS

Banks combine the savings of depositors to create a capital fund for business, mortgage and consumer investments. Numbers banks mimic this rhythm, first taking in the "savings" of the poor, then returning capital to the poor community in the form of usurious loans, free loans, philanthropy and direct business investments by racketeers. Therefore, numbers gambling banks are an irregular financial institution.

Prevailing economic conditions in black neighborhoods mutely suggest that numbers banks have not provided a level of financial service sufficient to sustain economic development, even though they helped to close a gap left by the chronic malfunction of mainstream financial institutions. Numbers banking did not, therefore, represent a "sensible, strong, and adequate response to environment" (Glazer, 1971: 42). From the point of view of local economic development and collective social mobility, the numbers-loan shark system is less efficient than rotating credit associations, another financial improvisation of urban blacks (Light, 1972; Bonnett, 1976).

This explanation extends and amplifies the strictly cultural view of numbers gambling which has hitherto prevailed in sociological literature. Numbers gambling of blacks actually reflects the conjoint influence of institutional as well as cultural causes. On the institutional side, the malfunction of mainstream financial communities in low-income communities creates a financial problem. Residents reach into their cultural repertoires for solutions. The solutions they extract have consequences for the rate and character of local economic development.

The case of numbers gambling suggests that cultural and institutional causes may operate in tandem, and their segregation in sequential all-cultural or all-institutional historical phases is not an adequate resolution of their tension. Cultural repertoires offer whole or partial solutions for institutionally-induced disabilities. Therefore, the institutional disability and the cultural solution coexist. When institutions obstruct, victims cope. There is no

reason to suppose that all victims' cultural repertoires contain the same remedies nor that all remedies have identical consequences. True, numbers gambling is a remedy, but a wasteful one; and the chronic malfunction of financial institutions which encouraged this remedy does not render numbers gambling a fully satisfactory alternative.

MANUSCRIPTS FOR THE ASA ROSE SOCIOLOGY SERIES

Manuscripts (100 to 300 typed pages) are solicited for publication in the *ASA Arnold and Caroline Rose Monograph Series*. The Series welcomes a variety of types of sociological work—qualitative or quantitative empirical studies, and theoretical or methodological treatises. An author should submit three copies of a manuscript for consideration to the Series Editor, Professor Robin M. Williams, Jr., Department of Sociology, Cornell University, Ithaca, New York 14853.

NOTES ON THE CRIMINOGENIC HYPOTHESIS: A CASE STUDY OF THE AMERICAN LIQUOR INDUSTRY*

NORMAN K. DENZIN
University of Illinois, Urbana

American Sociological Review 1977, Vol. 42 (December):905-920

This case study of a single economic enterprise, stressing a symbolic interactionist perspective, examines the five tiers which make up the American liquor industry: distillers, distributors, retailers, drinkers and the legal order. Consistent with the interactionist method, attention is given to the relationships and actions that constitute the worlds of this social structure. The alcoholic beverage and the drinker-consumer relationship is a central focus of attention from level to level within the tiers of the industry. Special attention is given to criminogenic activities within and among the five tiers of this industry. The historical context and social interactions from which these activities arise are given emphasis. Finally, a tentative schema is suggested for analyzing criminogenic activities within the American liquor industry and, perhaps, within other industries as well.

Whiskey and alcoholic beverages have been produced in the United States since 1640 and have been taxed intermittently by the federal and state governments since 1791. The 18th Amendment and the Volstead Act of 1919 stopped the growth of the industry and made the production of alcoholic beverages (except for medicinal, sacramental or scientific research purposes) illegal. While a few distillers remained in production under strict governmental control, the majority of distillers were driven out of business to be replaced by bootleggers (Sinclair, 1964; Gusfield, 1963; Kane, 1965).

OVERVIEW

In this article I wish to examine, from a symbolic interactionist perspective, the organizational development of the American liquor industry since Prohibition.

* I wish to thank Patricia T. Clough for her assistance in this research. Graduate students in Sociology 414-416 at the University of Illinois gathered ethnographic data on the public drinking establishments discussed in the text. Portions of this research were supported by the Graduate College Research Board and the Department of Sociology of the University of Illinois. The comments of Evelyn K. Denzin, Sidney J. Kronus, William Cockerham, Stanley Cross and Julian Simon were particularly helpful. Finally, I wish to thank Catherine Daubard for her assistance in the ordering and reconceptualization of the entire research question.

Blumer's (1969) proposals for the foundations of a theory of organizations suggest that the interactionist examines and stresses the informal, as opposed to the formal attributes of any organizational complex. Rather than viewing organizations in rigid, static terms, the interactionist sees organizations as living, changing forms which may outlive the lives of their respective members and, as such, take on histories that transcend individuals, conditions and specific situations. Rather than focusing on formal structural attributes, the interactionist focuses on organizations as *negotiated* productions that differentially constrain their members; they are seen as moving patterns of accommodative adjustment among organized parties. Although organizations create formal structures, every organization in its day-to-day activities is produced and created by individuals, individuals who are subject to and constrained by the vagaries and inconsistencies of the human form. Organizations ((including the licensed alcoholic-beverage industry) are best conceptualized as complex, shifting networks of social relationships. The sum total of these relationships—whether real or only symbolized, whether assumed and taken for granted or problematic and troublesome—constitute the organization as it is sensed, experienced, and acted upon by the individual or relational

member. Power, control, coercion and deception become central commodities of negotiation in those arenas that make up the organization.

Hamilton et al.'s (1938:3-4) image of an industry is well-suited to this analysis of the liquor industry. They remark:

In a literal sense, there is no such thing as an industry. . . . Instead . . . there is only a host of individuals . . . engaged in a varied assortment of personal activities—the digging of coal, the smelting of ore, the advancement of personal fortunes. . . . They are human beings who engage in human activities. . . . It is amid this babble of tongues, this confusion of purposes, this drama of divergent dramas that industry is to be found. . . . Yet industry is a name for what is at best a loose aggregate of business units engaged in performing a single service or producing a single commodity. . . . An industry is like an individual . . . it has a character, a structure, a system of habits of its own. Its pattern is out of accord with a normative design; its activities conform very imperfectly with a charted course of industrial events.

This investigation, starting from such assumptions, utilizes a case study method and focuses upon interactions and negotiations among members of this industry. Data have been drawn from all levels of the industry, but in particular the state of Illinois and the twin cities of Champaign-Urbana. The attention to negotiations among organizational members led directly and immediately to the consideration of criminogenic activities. I shall examine the extent to which criminogenic and quasi-legal behaviors have served the interests of the members of this industrial complex (see Bell, 1960; Gross, forthcoming). I hope to show that this criminogenic tendency (that is, the intended and unintended violation of the legal code) is present at all levels of the industry and can be traced to the historical context of the industry's development, to its present structure, and to the relational patterns which exist within what appears to be a single economic enterprise. Basic to the analysis which follows is the assumption that the organizational structure of any industry involves multiple tiers, levels or social worlds of interaction. Taken together, these multiple segments

constitute the organization as its members know it (Hamilton et al., 1938). Five such tiers, manufacturers, distributors, retailers, the legal order and drinkers, will be identified. Criminogenic activity evolves as a result of interaction among (as well as within) each of these tiers.

As one moves from the local level to the state, regional and national levels of the industry, the actual drinking transaction and the drinking act become less problematic. What emerges as problematic is the production, distribution and sale of a single product—the alcoholic beverage. This product—however bottled, branded, endorsed, packaged, priced or displayed—must somehow reenter the system where its last contender exited, be this the storeroom of the wholesaler, the shelves of the retailer or the refrigerator of the consumer. These two objects—one an actor (the drinker-consumer), the other a product (the alcoholic beverage)—emerge as central to the American liquor industry. They must be brought together, over and over again, and American society has given the liquor industry the license and mandate to join these two commodities in any of a variety of ways (Abrahamson, 1938:395-429).

HISTORICAL CONTEXTS

The interlocking effects of Prohibition and Repeal set the historical context for the post-1934 expansion of the liquor industry, and their enactment served to make the liquor industry a unique enterprise within the American marketplace.

Perhaps the most striking effect of Prohibition/Repeal was the concentration of alcohol manufacture in the hands of four large distillers—(1) Distillers Corporation (Seagrams, Ltd.), (2) Schenley Distillers Corporation, (3) National Distillers Products Corporation and (4) Walker (Gooderham & Worts, Ltd.). By the mid-1920s the Big Four had absorbed some 60 distillers in Illinois, Indiana and Kentucky (East, 1952; Oxenfeldt, 1951). The Big Four, unlike many of their smaller competitors, were able to survive Prohibition because, concomitant with their cushion of capital, (1) they were able to establish

or maintain Canadian bases of operation and/or (2) they were able to receive government sanction for the production of alcohol for legal uses (Oxenfeldt, 1951).

Prohibition and the public furor accompanying it convinced the large distillers that, if the production of liquor was to be not merely legal but also profitable, the public image of the liquor industry (and of alcohol consumption) must be transformed. This attempt at dramaturgical management took two directions: (1) to transform the image of the distilling industry itself which had been tainted by the violence and corruption of bootleg production and (2) to transform the act of alcohol consumption to a socially-approved act. The latter was especially important because temperance forces and anti-saloon sentiment among large segments of the population did not immediately dissipate with Repeal. The following statement well illustrates the tactic used by distillers to create a more favorable image for alcohol consumption:

In order to forestall attacks from various dry organizations, which the WTCU spearheaded, we emphasized one of the basic principles of the Distilled Spirits Institute [DSI]: moderation, moderate drinking. Don't over-sell, don't over-drink. [Frank Schwengel, retired brigadier-general and marketing advisor for Seagrams]. (Durrell, 1967:3)

A concomitant technique was to disassociate the distilling industry from tavern consumption. According to a prominent legal consultant for DSI (field interview, July 1975), after Repeal, distillers shifted from a saloon concept of consumption to a carry-home model. Distillers turned their economic efforts to the construction of a "rational," non-tavern, retail-outlet sales program.¹ By separating themselves from taverns, the distillers placated the anti-saloon-league advocates and succeeded in placing the blame for alcohol misuse upon the saloon drinker.

¹ Brewers were given taverns, or so it appears. As one distilling executive remarked, "There are only ten bars in Chicago where I want our product sold" (field interview, June, 1975). Today, approximately 75% of all alcoholic beverages are consumed in off-premise locales.

The passage of Repeal was proposed, of course, under the condition that not only would the production and sale of alcohol be legalized, but also that government regulation and taxation would be imposed. Much of the propaganda extolling government regulation and taxation (and, thereby, gaining support for Repeal) was financed by large distillers and brewers (Dobyns, 1940:6). For some groups, the economic benefit of alcohol taxation held sway. Much publicity stressed the loss of tax monies from liquor sales combined with the high cost of attempting to enforce Prohibition. Business, chafing under the taxation burden of World War I, was particularly susceptible to this argument and threw support behind the Repeal movement. Propaganda, supported by the large corporations (particularly DuPont), went so far as to promise that the recent and unpopular income tax could be eliminated by the use of tax monies from alcohol. Other groups, even some sincere temperance groups, were influenced by the supposed benefits of government regulation. The argument was emphasized that Prohibition bred more social ills than it cured and that the bootleg trade was far more detrimental than would be a well-regulated, legal industry (Dobyns, 1940:19-27).

It was hoped that a conciliatory attitude toward regulation and taxation by the distilling industry would pay off in the long run by moderating public opinion of the industry itself and of alcohol use. In the meantime, the liquor industry encouraged government control as the price it was willing to pay for legalization.

As it turned out, government regulation never proved to be much of an inhibition to profits. One reason for this was that the liquor industry itself helped to write the rules. Within ten days of ratification of the 21st Amendment, a Code Authority was created, consisting of the top executives from the large distillers. President Roosevelt directed the Code Authority to draw up a set of guidelines for the federal regulation of their industry. Owsley Brown (president of Brown-Foreman Distillers), L. S. Rosensteil (Schenley's) and Frank Thompson (Seagram's) created the Distilled Spirits Institute (DSI). In the im-

mediate post-Repeal days, the industry, through DSI, worked closely with the federal government—a government-industry relationship which may be without precedent in American history (Durrell, 1967).

DSI encouraged high government regulation and taxation as a cover behind which to hide and reform their collective self-image. While appearing to meekly accept a weak position, they learned from their industrial counterparts in oil, railroads and automobiles how to cover their ever-expanding behaviors through the newly emerging and complex antitrust laws. The liquor corporations kept a low profile, concentrated on dramaturgical management, and busied themselves behind the scenes in the direction of vertical and horizontal integration. Furthermore, Repeal put a great deal of the responsibility for regulation of the liquor industry upon state and local officials (as well as national officials). This placed liquor corporation representatives in a situation where they could corrupt the very persons who were intended to control them.

A final consequence of Prohibition/Repeal was that government regulation introduced what came to be termed the *three-tier system* of distribution in the wine and spirits industry. Under this system,

the three levels of supplier, wholesaler and retailer must be maintained separate and independent of each other, and the supplier must sell only to the wholesaler, and the latter only to the retailer. The wholesaler, therefore, stands between the retailer and the manufacturer. (Switzer, 1975:5)

Hidden in the above language is one basic point which had been the touchstone of the Anti-Saloon League; namely, that distillers and brewers owned, or staked tavernkeepers, imposed quotas upon them and forced them to take money out of the pockets of family men (Sinclair, 1964; Gusfield, 1966). "Tied taverns" or "tied houses," as they were called, permitted outside interests to control the politics, moralities and drinking patterns of local communities. By placing the wholesaler between the manufacturer and the retailer, the state and federal governments attempted to break the tied-tavern relationship—at least on the surface.

OBDURATE REALITIES

At the national level, Repeal produced a complex set of laws and procedures unique to every state in the United States (see Distilled Spirits Council, 1974). These procedures include tax and its collection procedures, size of retail containers, local option rulings on retail sales and license permits for distillers' representatives. Also at the national level, antitrust laws and federal tax statutes² set boundaries for corporate activity.

At the state level, each State Liquor Commission sets the regulations and modifications of the three-tier system of distiller, distributor and retailer. There are two state models. *Monopoly states* permit the sale of bottled distilled spirits only in state-owned stores. *License states* are states where distilled spirits are sold under a licensed, private enterprise system. This system operates with three variations. For example, in Illinois distributors are given territorial monopolistic rights for the distribution of a particular brand-name product. In addition, licensed resident manufacturers (rectifiers) may sell beverages manufactured within the state directly to retailers (Switzer, 1975).

States also set minimum age limits for consumption of alcoholic beverages and, in some states, this may be differentiated between hard liquor and beer or wine.

At the local level, local liquor commissions (which in Illinois are headed by the mayor) set laws regulating the number of and fees for liquor licenses, decide who receives liquor licenses, and define operating procedures for retail establishments (i.e., hours of operation). Local communities also may set limits such as

² Government taxation and regulation created a dual effect upon the current system. Liquor taxation is the most expensive factor in producing every gallon of distilled alcohol. Federal taxation is \$10.50 per gallon, state tax may be as high as \$2.50, and some communities impose a local option tax. This situation causes distillers to comment that the cheapest product in their industry is the alcoholic beverage. Because federal and state taxes must be paid by the distiller before the product leaves his warehouse (i.e., before payment of account), the liquor industry is a high capital, low-labor business—a characteristic which discourages competition from small-scale entrepreneurs.

minimum age for consumption of alcoholic beverages and impose a local excise tax on alcoholic beverages.

These legal procedures, variably enforced and understood, influence the operation of this industry at every tier-level. Such codes also define the circumstances for criminogenic behavior at each level. Members of one tier may be unaware of, or only partially understand the laws which apply to any other tier. In addition, they may be unaware of, or misunderstand those laws and regulations which apply to their own level (field interviews, 1975).

FIVE-TIER STRUCTURE OF THE AMERICAN LIQUOR INDUSTRY

As Hamilton et al. (1938:3-4) observed, there is no such thing as a single industry. At least five different tiers resolve into distinct social worlds which constitute those collective realities that make up this particular industry. The 21st Amendment recognized the three tiers of distiller, distributor and retailer. Closer inspection reveals the presence of two additional tiers: first, drinkers themselves and second, those individuals and agencies committed to the enforcement of the liquor laws—state and local liquor commissions, the police, the FBI, the Treasury Department, and the Bureau of Alcohol, Firearms and Tobacco (BAFT).

Distillers

At the executive level of rival distilling firms, hostile, not cordial or congenial relationships appear to be the pattern, although these participants will seldom permit personal animosities to enter into profitmaking decisions. Oxenfeldt (1951:478) notes that the executive offices of the large distillers are all located in New York City, within a short radius of one another. (There has been a recent regional shift to Chicago.) The executives meet often and know one another well. With few exceptions, they belong to the same organizations and clubs, including DSI and the Licensed Beverage Industries Institute. They also contribute to the same

charities, all in the collective name of the industry. Oxenfeldt (1951:478) states:

There is no close personal friendship between the top executives of the major distilling corporations . . . their relations vary somewhere between friendly rivalry and intense personal antagonism.

Conversely, separate distillers tend to be tightly bound through kin relationships. Of the four major whiskey producers, all but one are family controlled, with control extending into pre-Prohibition days. (For an illustration of one such family, see Gaines, 1975.) The same pattern appears to hold for brewers and wineries, at least until quite recently (see Horowitz and Horowitz, 1965).

Two highly visible phenomena at the distilling level are the emphases placed upon in-house legal advice and upon advertising. Every major distiller, brewer and vintner employs a legal staff. Its chief function is to monitor the changing laws within each state, to keep in touch with relevant legal representatives of the industry, and to represent the best interests of the industry to local, state and national political entities. They ensure that their corporations do not grossly violate any statute or ruling that would inhibit the sale of their products. These staffs also enter into negotiations with distributors when territorial contracts are reviewed annually and new quotas set (see Distributor section).

The respective advertising arms of the industry bid against one another at the agency level to capture ever-larger drinking audiences (Bretzfeld, 1955; Simon, 1969). Advertising points to perhaps the largest and most heterogeneous sector of the liquor world: the drinker, the ultimate point of contact for all the interactions that make up this world. The drinker can make or break new programs. His purchasing patterns determine package programs and advertising campaigns, and his shifting moods—regarding taste, product and brand—enter into the long-range planning programs of the distiller, distributor and retailer.³

³ One example will serve to highlight the centrality of the drinker-consumer in this process (but also see

Distillers also engage in product promotion within their own ranks. One distiller gives its corporate executives a "Friday package" which consists of a bottle of gin, vodka and blended whiskey. This is expected to last one week, and they are expected to display these products when they host social occasions. Each Friday afternoon at 4:00 PM these executives leave their offices with their gifts wrapped in brown paper bags. Their corporate identity is maintained, although the price of their gift is hidden (field interview, July, 1975).

The most striking characteristic of the distiller level is that such activity is a huge and complex concern, national and even multi-national in nature. Large corporations view themselves as Big Business and define their activity as modern, "rational" promotion of a product similar to any other product. The attitude of the modern corporate executive toward his product equates the sale of whiskey, beer and wine with the marketing of standard grocery items. The vice-president of sales for a large corporation which holds sole United States rights to import one of the four top scotches in the world remarked, "Scotch is no harder to sell than shoestrings or overalls. It's a matter of marketing, promotion and packaging" (field interview, July, 1975).

Distributors

As in the distilling tier, family ties bind many of the distributorships in the area studied. Eight of the ten wholesalers in the

seventeen-county area under consideration (downstate Illinois) are related either through marriage or direct kin lineage.

The most important advertising commodity or medium for the distributor is the street salesman. He or she links the distributor to the retailer and thereby connects the customer to the distiller. Distributors (through street salesmen) must court retailers to maintain a clientele, and this courting process takes the form of special attention, extra visits and other favors. Distributors are required, at the same time, to conform with state regulations. For instance, the state of Illinois demands that all beer be paid for upon delivery and gives 30 days for all other alcoholic products. If a retailer or tavern owner fails to meet a payment deadline he or she goes on a delinquent payment list that is filed in the state capitol each Wednesday. No distributor can legally deliver to a retailer whose name is on the delinquent list.

In Illinois, distributors typically receive a territory for the sale of a particular distiller's products. Wholesalers cannot sell outside of their territories, but the agreement is that only one contract will be awarded per territory. Territories, however, are not always clearly boundaried, and wholesalers often find themselves in a situation where a particular distiller has "dualled" their territory (such a move may also be a threat or attempt to force the distributor to meet higher quotas of product sales). This means that two wholesale houses are in fierce competition to sell the same product to the same retail outlets. "Dualing" leads to deals in an attempt to control territories.

At the state level, the distiller is supposed to verify his territorial commitment to specific distributors by annually filing a list of accredited distributors who can sell his products. Typically, in order to obtain such a territorial monopoly contract, distributors must meet quotas. When contracts are terminated, termination is generally initiated by the distiller, who will argue that the distributor has not given his product sufficient attention over the last sales period. Since the distributor depends on distiller contracts, he must move a certain amount of the product to survive. He

the discussion of street salesmen in the Distributor section). After eight years of planning, testing and field experimentation, Heublein, Inc., in the fall of 1975, introduced a new product named "Hereford Cow" which comes in chocolate, mocha and strawberry flavors. Aimed at youth, it was introduced simultaneously in two test cities, Champaign-Urbana and the South Side of Chicago. Hereford Cow was forced onto the shelves of all the bars served by the local distributor (see discussion of off-invoicing). Within four weeks it was rejected by all bars. While its initial sales in South Side Chicago of 150,000 cases in two weeks far surpassed expectations, it has since dropped off in sales. Heublein is searching for a new product for this particular audience (field interviews, August, 1975).

must convince retailers to stock a certain amount of that distiller's products. At the same time, if the retailer feels that he is being overloaded with unsaleable products, he is likely to take his business elsewhere. In this way, the street salesman must help the retailer to please his customers. However, the distributor can be caught between the public and the distiller. One example comes from a street salesman who serves small racial and ethnic retail liquor outlets in South Chicago. The drinkers in this area prefer to purchase (in pint-sized quantities) only the most prestigious scotches, bourbons, gins and vodkas. However, they change their taste patterns almost weekly, leaving the salesman either understocked or overstocked for his outlets. (This drinker, who comprises over 50% of the drinking population in Washington, D.C., Chicago and New York City, is particularly problematic for the distilling industry [see *Liquor Handbook*, 1975].)

Some distillers do, however, attempt to establish distributor loyalty to their prime items. One major distillery has an exclusive club to which only presidents of distributorships can belong. Membership in the club is passed on from father to son; hence, the name "Happy Sperm Club." Should a father fail to produce a son, he must marry his daughter to a male who is willing to enter the business. Once the male heir assumes control, the father relinquishes his membership in the club. A common practice of this club is to schedule a two-week vacation in some exotic resort area for distributors. Such notables as Gloria Steinem, Tom Hayden, Huey Newton, Merle Miller, Walter Hinkle, Bill Cosby and Don Rickles have lectured and entertained at these functions.

Distributors represent the weakest link in the three-tier model. They can be rejected by retailers or find themselves either "dualled" or without a contract from the distiller. They are in a poor bargaining position and are under constant pressure from the distiller to meet new quotas. Retailers can turn elsewhere; without distiller contracts, franchises and retail accounts, the distributor is out of business.

Retailers

Retailers include both package outlets and on-premise sales (taverns). In 1944, 34 families controlled 60 of the 80 local taverns in Champaign-Urbana. Since then, the number of taverns has more than doubled and the same families control a large proportion of these enterprises. One family controls all but one of the six local retail sales outlets (excluding grocery stores and drugstore chains). That family now has a virtual monopoly on retail sales. Family control typically extends through three generations. Intense family loyalty is engendered and a kind of entrepreneurial pride characterizes these industries. For instance, one of the principal liquor retailers in Champaign-Urbana, when asked to comment on his chief competitor, stated, "It is my goal to drive that SOB out of the business. Even if I have to lose money on a particular deal, I will make a fool out of him." Retailers also disrespect outsiders who rely upon chain-store assistance in the sale of alcoholic products. A large up-state retailer remarked,

I started in 1934 with a corner shop and couldn't even get a sign in the door. I paid \$200 a month rent. I paid off the bootleggers, the police; I kept up my bills. I didn't let the outsiders drive me out. What do these people in the chain stores, the grocery stores and drug stores think they can do? They don't know the business. They'll never drive me out. (field interview, June 1975)

The modern retailer reads the *Liquor Store Magazine* (1974). He permits the distiller to rent shelf space in his store for prominent display of products. He thinks in terms of more efficient ways to increase profits.

The retailer must renew his license annually. When licenses are renewed (they cost from \$1,250 to \$1,500), the applicant is fingerprinted; local liquor commissioners use this occasion to remind the applicant that it is a special privilege to hold such a license. Licenses can be suspended from two to thirty days, typically for serving underage drinkers; and holders of liquor licenses cannot hold elected public office in the state of Illinois.

The local retailer feels a resentment

toward the legal order, feeling that it deprives him of his political and economic rights. They resent the outside chain-store entry into their market. (Between 1967 and 1975, the number of retail licenses in Champaign-Urbana doubled, especially those for the off-premise consumption of beer, wine and distilled products. All but two of the new permits went to grocery and drugstore chains.)

While retailers must maintain a cordial relationship with the local legal structure, the nature of their business often demands that they engender a regular clientele. These two demands can conflict with each other, as when drinkers resent being asked to show proof of age or to wait in line while others do so. Bars or taverns often find that they must create a unique social world within their establishments to produce patron loyalty. One means for doing this is to adopt or manipulate the relevant social objects or symbols of the clientele they wish to attract. This can include the display of fraternity mugs and paddles, holding "playboy bunny" nights, sponsoring intramural football teams and, in some cases, hiring university football players as bar bouncers. This serves, in part, to connect the bar with the university's athletic department.

Drinkers are often regarded by bar owners as fickle. One local bar which had been existence for 25 years changed hands in the summer of 1975. The new owner, whose father had in fact owned the property, completely changed the decor and pinball arrangements in the "new bar." He immediately lost a regular crowd that had roots going back 25 years. He is still in the process of regaining that lost crowd.

The retail level connects most directly with the drinker. The retailer must, however, negotiate with all other tiers in the industry. It is the most conspicuous, yet perhaps the most complicated tier of all.

The Drinker

The drinker is the presence behind every other tier. Studied, courted, deceived, he keeps the system going. As we shall show later, distillers, distributors and retailers routinely violate or challenge the civil-legal code, yet are seldom taken

to court. It is the drinker who receives the most direct scrutiny by law enforcement officials and who is the most likely participant in the system to bear the legal burden of illegal production, distribution, sale and consumption. The drinker's use and misuse of alcoholic beverages serve as a reminder that the object called alcohol is consumed and acted upon under a variety of social definitions and circumstances, some of which lead to unlawful behavior.

The Legal Order

The legal order consists, at the *local level*, of liquor commissions, the police and the courts. Retailers and drinkers receive the closest surveillance at this level. At the *state level*, state liquor commissions monitor the conduct of retailers, distributors and distillers. At the *national level*, BAFT, the FCC and FTC, and the Treasury Department (more generally) are responsible for locating illegal liquor transactions.

The federal and state monitoring of liquor laws and liquor violations is weak. In Illinois, at the state level a six-person Liquor Control Commission, consisting of a president, secretary and director plus three adjunct members, oversees the operation of the state's liquor code. This commission is reappointed after each gubernatorial election and has a nine-member investigative team that covers the entire state. The federal government, except through the understaffed operations of the BAFT and FTC, is also in a weak position to monitor violations of the liquor codes. The failure of the state and federal governments to cooperate has led to a situation that currently is being exploited by organized crime (Cecil, 1974:2).

At the local level, at least in theory, the administration of the civil-legal code is much more intense. The fact that all enforcement branches (liquor commissions, police and courts) may be intertwined politically potentially can mediate and distort the function they are intended to fulfill.

At the legal level, the liquor industry is a very loosely-monitored, semi-understood and taken-for-granted system,

as the following interview with the previous president of the Illinois Liquor Control Commission reveals. When asked about Regulation 6, Article 4, which requires that all distillers place on file the territories wherein they have granted distributors exclusive sales rights, he remarked, "I have never heard of the rule; if it was important I would know about it" (field interview, June, 1975). A prominent legal consultant for the distilling tier confessed that often members of the state liquor commission call *him* when they have questions concerning the meaning of the law. Certainly, few drinkers are aware of the laws that limit the number of retail outlets in any city, nor are the prices of licenses commonly known. Additional complexity is introduced when multinational corporations buy up specific distillers and purchase exclusive sales rights to specific brands. One retailer remarked, "You never know from day to day who owns these damned corporations or what their policies are" (field interview, August, 1975).

TIERS: COOPERATION, COMPETITION AND CRIMINOGENIC ACTIVITIES

The present research focused on the organizational development since Repeal of the five tiers of the industry, with special attention given to criminogenic activity, be these behaviors of omission, commission, evasion or outright illegality. We shall examine such behaviors within each tier as well as those which emerge from the interrelationships among tiers.

Repeal opened the way for a small group of distillers at the national level to capitalize on a relatively new and ambiguous situation. Not only did they have to redefine themselves for the federal government, but they also had to formulate a collective image of self that could be sold to the public. The following discussion of each tier suggests that the industry has succeeded in becoming an institutionalized American economic industry. Gross instances of corruption and illegal behavior became clouded behind complicated corporate laws and local statutes. In the end, drinkers, tavern owners, retailers, wholesalers, manufacturers and

the legal structure all profited. Deception and illusion became marketable commodities. Bootleg liquor gradually disappeared and up-graded alcoholic products appeared on the market. A normalized system that assumed a taken-for-granted nature emerged, was solidified and, gradually, became institutionalized into local, state and national laws.

The multi-tiered liquor industry in the mid-1970s appears to be a highly stable enterprise. However, hidden behind its interactional structure are a variety of criminogenic activities, usually quite deliberately calculated, which economically benefit one or more participant or tier in the system. The economic benefits are not confined just to profit margins on the stock market, nor to the dollars produced by a single bar or retail outlet at the end of a year. Rather, the economics of the liquor industry translate into private, personal economies of style, career, prestige, power, collegiality and friendship. At each tier, different economies are battled over. This produces different criminogenic activities at each level. Often clouded behind elaborate symbolic campaigns and structures—e.g., a new drink for the young urban sophisticate—the industry and its participants enhance their own positions at someone else's expense. The competitive interactions that tie tier members together encourage intra-industry exploitation and criminogenic conduct (Benson, 1975; Gross, forthcoming). We shall present evidence in support of this argument, beginning with the distiller who is the most powerful force within the industry.

Distillers

Distillers violate as well as challenge antitrust laws. Large corporations can hide behind complicated corporate structures which allow them to gain major holdings in competing lines or to diversify within the same product line.

A case in point is offered by the history of Heublein, Inc., which produces vodka, mixed cocktails, dry gin, cordials, beer, rum, table wines, sherries, and all wines sold under the names of Italian Swiss Colony, Inglenook, Lejon Petri and Gam-

barelli & Davito. Subsidiaries of Heublein, Inc. include Allied Grape Groups (82% controlled), United Vintners, Inc., Kentucky Fried Chicken Corporation, Heublein (Canada, Inc.), Heublein International Ltd. and Smirnoff Beverage & Import Company. The 1968 acquisition of controlling interest in United Vintner's Inc. led the FTC to issue a complaint that Heublein's was in violation of the Clayton Anti-Trust Act. Heublein's denied the charge, asserting that its interest in United Vintner's gave California grape growers a marketing edge to meet industry competition. The FTC dropped its charges.

Major distillers, such as Heublein's, flirt with antitrust laws. They are seldom brought to court, and when they are, high-ranking corporation executives often profit by relinquishing their shares in a competing corporation for a handsome profit.⁴

Distillers often negotiate with one another over the relative prices they will set for their respective products. Federal law requires that no distiller market a product at a price lower than the price he lists at a designated time in an affirmation state. Deceit, deception, misrepresentation and "unintended leaks" of information abound at these times. At least one large scotch manufacturer is now under suit for his latest filing procedures. Lax monitoring at the state and national levels leads members of the industry to sue one another over pricing procedures and pricing violations. In this sense, they police themselves.

Not only do manufacturers violate antitrust laws but they also exert excessive pressure to meet quotas upon distributors

who, in turn, pass this pressure along to the retailer. In response to such pressures, retailers often deceive the customer into believing that he is getting a good buy on a particular product. A specific problem that ties the distiller to the wholesaler and to the retailer is the *off-invoice strategy* which arises from competition among wholesalers. Distillers put pressure on wholesalers to move a particular product by threatening to withhold supplies of a top-selling item. They demand that wholesalers buy more of this product than they can normally move in a month's time. To get his money out of the unnecessary inventory, the wholesaler will give retailers extra liquor, off the invoice, as long as the retailer buys a portion of the premium liquor. This violates several laws. The retailer may make the sale, not ring it up on his cash register and, thereby, avoid federal and state taxes. The wholesaler, who has paid the proper taxes on the products he has received, violates federal and state laws by keeping a second set of books which falsify his invoice orders to the retailer (see Farberman, 1975, for a similar instance in the auto industry).

A third form of distiller-manufacturer behavior, which does not violate any specific laws but which deceives the customer, is the practice of *multiple branding*. Abrahamson (1938) reports that distillers believe that consumers have only the haziest notions of the differences between whiskeys. Accordingly, the more brands a distiller can offer, the greater the likelihood that he can capture a broader sector of the market. In 1951, it was estimated that there were over 30,000 rival brands of whiskey on the national liquor market which were controlled by less than 40 separate distillers. Single companies may have as many as 50-100 different brands. National Distillers markets ten brands of bourbons, each appealing to a different audience, each marketed by the same distiller. Immediately after Prohibition, when the stock of aged whiskey was at an all-time low, blended whiskeys came on the market. In order to encourage the purchase of their products, distillers prefaced all their labels with the word "old"—thus, Old Taylor, Old Rip Van Winkle, Old Charter, etc. (Abrahamson, 1938:414).

⁴ A former president of a major United States distillery gave the following information in an interview, July, 1975.

In 1934, his brother joined forces with a Canadian distiller and they profited greatly in post-Prohibition days. In the 1950s, the brother joined another firm which acquired the rights to a particular brand of scotch. At that time, the firm held controlling shares in the three top-selling scotches in the world. In 1968, the FTC brought an antitrust suit against his firm. The antitrust suit was tied up in the courts for six years. The FTC won and forced him to sell his shares in the company. He sold his shares for a 50% profit. The result of the FTC's suit was to make profits for the offender.

Branding produces product identification, which is intended to produce self-identification on the part of the drinker. The distiller endeavors to cultivate drinkers who will purchase only prestige items. The distiller manipulates the drinker and attempts to maintain the illusion that certain brands are still distilled by the same families that originated the product. Most, if not all, original scotches and bourbons initially tied to specific families have long since been purchased by large-scale corporations who simply maintain the original brand name and label.

Quasi-tied houses represent a third form of distiller-brewer manipulation of the legal code. While the three-tier model prohibits the intervention of the distiller-brewer in the actual sale of his product, informal agreements arise which tie taverns to manufacturers. This tie is made through the wholesaler (who himself may be tied to a particular distiller or brewer) who does favors for tavern owners. Wholesalers make special runs. They stop by up to three times a week to chat with tavern owners and managers. They fill special orders and make special deals to favored customers. A *norm of reciprocity* (Gouldner, 1959) is expected to operate. In return for special services, the tavern owner is expected not to solicit or to indulge in the services of another distributor, even if his "tied" distributor cannot deliver the products he needs. This norm locks the tavern owner into a compromising and, at times, uneasy relationship with the wholesaler.

Distributors

As noted earlier, distributors are prohibited from selling outside their prescribed territories. However, *territorial violations*, in which distributors cross one another's territory and make illegal sales, represent a frequent form of illegal behavior on the part of the distributor. A *norm of silence* operates; one will not tell on another wholesaler if that one will not tell on him. Similarly, retailers who can make profit purchases are not about to report that they bought from a wholesaler outside their territory. (In Illinois, there is

the famous rumor of a 4,000-case purchase of a Canadian blended whiskey by a retailer from a distributor who was 200 miles outside his territory. The retailer, one of the largest in the state, could laugh about the matter and the wholesaler in question could deny it. The case was never investigated.)

Distributors can negotiate with one another. In Champaign-Urbana, in response to a recent labor strike at the Anheuser-Busch factory in St. Louis, the local distributor holding the sole rights to Busch products found himself out of stock. He began selling what he termed "brand X" which, upon inspection, was found to be Old Style beer. The local Old Style distributor denied selling it to the Anheuser-Busch distributor. The matter came under brief investigation by the Executive Director of the State Liquor Commission but nothing came of it (Weiss, 1976). Some distributors agree to ignore infractions and permit each other to serve old customers, usually family friends, who reside in another's territory (field interview, September, 1975). Such agreements engender goodwill and lead distributors to help one another out when they find themselves short of some needed product.

Distributors must negotiate the payments they receive for delivered goods to retailers. As mentioned before, all beer must be paid for upon delivery and all other alcoholic products within 30 days or the retailer goes on a delinquent payment list. No wholesaler legally can distribute to a retailer whose name is on the delinquent list. However, *delinquent list manipulation*, in which a distributor withholds a name from his delinquent list, constitutes another semi-illegal act on the distributor's part. Variations include rebuying overstocked products with kickback funds or extending illegal credit to a retailer by doctoring the invoice books.

The *Wall Street Journal* featured an article noting that distributor kickbacks to retail stores seem common in New York City (Kwitny, 1975). The author notes that at the wholesale level: (1) salesmen carry cash from store to store to give kickbacks to retailers; (2) wholesalers ship free loads

of whiskey to retailers and account for the missing merchandise by reporting a warehouse theft; (3) distributorships list salespersons who receive high commissions which actually go to retailers who patronize certain houses; (4) some wholesale houses print lists indicating the amount of kickback money that is available when a retailer purchases certain products.

Distributors also can make agreements with specific retailers or tavern owners to supply them with specific goods or services, any or all of which may be illegal or semi-illegal. In 1944, the Illinois Liquor Control Commission Code made it illegal for any distributor to provide a tavern owner with walk-in coolers, free glasses, free calendars, clocks, bar equipment, mirrors or outside display signs. The economic slump of 1971-1974 led distributors to begin enforcing this law informally, telling their favorite tavern owners that "the feds had come down on them and they could no longer provide these services" (field interview, August, 1975).

Retailers

The retailer is the most entrepreneurial and independent operator in the system and is, thereby, most free to manipulate, deal and negotiate agreements that are in his own best interests. Retailers who achieve sufficient size are in an enviable position for they can control wholesalers and exert pressures through wholesalers back to the manufacturer. Some retailers bypass distributors and deal directly with the distiller—a direct violation of the 21st Amendment. Retailers can manipulate distilling corporations into making special deals with them simply because they can move large volumes of a particular product. In some situations, a retailer can make arrangements to be served by a distributor who actually resides in another territory. In these instances, the size and power of the retailer lead him to take control over the local market distribution of a particular product. In one instance, a retailer virtually controls both a wholesale house and a distilling house. He buys outside his territory and refuses to permit his major distillers to deal with his chief local com-

petitor. If they deal with that individual, he threatens to cancel all contracts with the house in question.

Such illegal and semilegal behaviors enable community retailers to amass the power necessary to control local competition. A retailer bent on running a competitor out of business can, through deals, buy a product in sufficiently large quantity to systematically undersell his competitor.

Retailers can negotiate with one another, i.e., they may agree to set a bottom price on a certain product. Groups of tavern owners may agree to take a hard or soft line on the enforcement of the legal drinking-age law and they may or may not cooperate in the organization of a communication network that warns fellow bar owners of an impending police raid. Retailers can agree to cater only to certain drinking audiences and in a campus town such agreements often flow along the organizational lines of housing units, sororities and fraternities. On the other hand, outright battles may occur when a new bar owner enters the public drinking arena and attempts to take stable patrons from other bars.

Many tavern owners violate the laws every day. They serve underage drinkers and they fail to meet local building, sanitation and wiring codes. Bribes to building inspectors are not uncommon, nor are bribes to the local political structure. Tavern owners' violations come under the direct scrutiny of local liquor commissions, and they are frequently monitored by police departments through raids and periodic checks. Retailers are in a direct position to receive kickbacks from distillers and wholesalers as well as being the beneficiaries of delinquent-list manipulations. In a similar fashion, tavern owners and retailers give preferred customers charge accounts and reduced prices on certain beverages. Both practices are prohibited by local statutes.

The Legal Order

The political administration of local statutes can permit preferred citizens to obtain liquor licenses when others are denied such privileges. Blocks of votes can be purchased when local, state and national

politicians take stands on expanded liquor-licensing or increases in the tax on alcoholic products (see Henderson, 1934; Anderson, 1976).

Rubenstein (1973:420) has made the following observations (based on his field work with the Philadelphia Police Department from 1968 to 1971) on the politics of liquor control:

The state monopoly over liquor licensing has converted the right to drink into a source of political capital—cash and favors—which is exploited by state and city governments and their agents, the police, to assure compliance with their interests. Politicians exact enormous fees for selling and transferring lucrative licenses, and the police are obliged to maintain the efficacy of the system by harassing those who do not adhere and protecting those in favor.

Rubenstein could be describing several cities in the state of Illinois. Consider the following on the shakedown of tavern owners in the city of Chicago:

Former County Board Chairman — was found guilty on two charges that he shook down tavern owners in exchange for issuing or renewing their liquor licenses. . . . — has been accused of extorting \$17,500 from [two tavern owners] in exchange for helping [tavern owner] obtain a liquor license. (Fisher, 1976)

In Champaign-Urbana, the prices for liquor licenses, which nominally cost between \$1,250 and \$1,500 depending on the class of liquor type, were reported to range from \$500 to \$20,000 (field interviews, June-August, 1975). One individual reportedly received a second tavern with a renewed license in return for giving up a license. One applicant told interviewers he had been assured he would receive his license and proceeded to engage in expensive modifications of his new drinking establishment. Well into the project, he was informed that his license application was problematic and he would have to "speak to" certain persons about his proposed license (field interview, June, 1975).

At the local level, corruption, payoffs and conflicts of interest can be observed in any of the following areas: (1) license applications, (2) license renewals, (3) protection of licenses, (4) protection against raids and (5) alterations of zoning laws so

"dry" areas can be converted into "wet" areas where new licenses can be awarded.

At least two tavern owners over the last 30 years purportedly were driven out of business because they refused to "protect" their licenses. In another report, a dry township was converted into a wet township (as negotiations were underway to establish a large out-of-town shopping center) by the movement of a construction worker into the dry township for one month. A construction firm set up a house trailer for him and paid all his expenses. At the end of the month he called for a referendum to vote the township wet. Since he was the only resident in the township, the vote carried. The owner of the construction firm was a local politician.

The Drinker

Space prohibits any detailed discussion of the drinker as a separate tier within the American liquor industry (for a recent review of the drinking pattern of Americans, see Liquor Handbook, 1975). Observations gathered from distributors, retailers, tavern owners, distillers, importers and brewers do, however, support the following conclusions. First, the American drinker is a willing supporter of the industry that produces the alcoholic beverages they consume. That is, they purchase what is offered to them. Second, they are somewhat cynical, if uninformed, about the products they purchase. Third, the everyday drinker has little knowledge of the complex interactions that bind bar owners, retailers, distributors, distillers and the legal order to one another. Drinkers assume that the products they desire will be present when they want them. Laws, codes, liquor commissions, territorial boundaries and tied houses are not relevant realities for the drinker. The complex social structure that brings a particular brand of bourbon into the hands of a drinker is unknown or only barely glimpsed. Yet that structure exists because the drinker *qua* buyer assumes it will exist. The success of the industry has been, and continues to be based on the actualization of this assumption (see Cavan, 1967; LeMasters, 1975; Roebuck and Frese, 1975).

SOME NOTES ON
CRIMINOGENIC BEHAVIOR WITHIN
THE AMERICAN LIQUOR INDUSTRY

This case study of a single economic enterprise, stressing a symbolic interactionist perspective, has examined the five tiers that makeup the American liquor industry. Consistent with the interactionist method, attention was given to the relationships and actions that make up the world of this social structure. The alcoholic beverage and the drinker-consumer relationship constituted a basic focus of attention from level to level, tier to tier.

Any discussion of criminogenic behavior is complicated by the fact that there is no clear-cut theoretical consensus of what constitutes a criminogenic act. It can be assumed, however, that in order for a criminogenic act to be produced, an individual or corporate structure must (1) be in a situation wherein they have the *opportunity* to produce such an act, (2) have the *means* at their disposal for producing that act and (3) possess a *motive* or explanation to account for that behavior.

Although a discrete theory of the emergence of criminogenic behavior within a complex organization is beyond the scope of this paper, a few tentative observations which fall within the schema suggested above can be made.

Opportunity

Concealment, by secrecy or ignorance or both, appears to be a factor in some illegal and semilegal acts whose existence depends upon being hidden, either from other tiers or from the general public. Multiple branding, price fixing, or conflicts of interest are examples of behaviors which would not bear close scrutiny. The family bonds within the tiers of distiller, distributor and retailer probably facilitate concealment.

Perhaps the most striking characteristic of the liquor industry is *complaisance* on the part of the drinker-consumer. The drinker, although cynical, appears to find the convenient delivery into his hands of the desired alcoholic beverage to be the most relevant reality. Throughout the industry, although most participants assume

that the legal code is broken, few individuals care to pursue the matter. This may be particularly true for within-industry behaviors such as territorial violations, but it also appears to hold true for such illegalities as sale to minors, complicity of the political system and protection of licenses. Like organized crime, the liquor industry depends upon delivery of a product whose procurement is desired and whose price does not exceed what the customer is willing to pay (Vold, 1958:227). The liquor industry, as Al Capone suggested, is a "legitimate racket" (Sutherland, 1940:12). Although complaisance appears to contradict the role of concealment, this may be only a superficial paradox. The rule of the game appears to be that participants will close their eyes to all but the most obvious of indiscretions.

The complaisant and taken-for-granted attitude, both within and without the industry, taken toward criminogenic activities suggests that below the articulated legal structure there exists an *informal structure*, one which often contradicts or supersedes the formal structure. The informal structure may define as "legal" activities which are defined as "illegal" by the formal structure. The taken-for-granted reality of the former legal order is, perhaps, more illusory than it is concrete.

Means

The efficacy of many regulations depends upon accurate *self-reporting* by levels within the industry itself. Distillers supply figures for tax accounts, distributors are responsible for delinquent-list reporting, and retailers share in accounting for invoice figures. *Scarcity of penalties* and *weak enforcement* of laws often allow the industry to operate unmolested. *Structural ties between the political order and enforcement agencies* (such as those between local liquor commissions and the police) belie separation of power between legislation and implementation. Such ties collapse into one unit—the liquor industry—the essential ingredients of power, control and corruption. Bribery of officials (or shakedown of

retailers, depending on the viewpoint), protection of licenses, and alteration of zoning laws are particularly applicable in this category.

Motive

The multi-tier nature of the liquor industry seems to be linked to both crimes of competition and crimes of cooperation. Obdurate realities for each tier appear to be quite distinct and to create problems unique to participants within the same level. Individuals within each level often referred to themselves as "we" and definitionally aligned themselves with other members of the same tier. This *quasi group solidarity* may produce cooperational crimes such as price fixing, mutual concealment of violations and warnings of police raids.

Alienation from the law (usually the feeling that laws are unfair or unrealistic) also appears to be linked to crimes of cooperation, especially those which require cooperation between tiers to circumvent the law. Consensual definition of regulatory codes as "out-of-date" or "crazy" was used, directly or indirectly, as an *a priori* justification for breaking or bending the law (field interviews, 1975). Further, the widespread attitude among all levels that the liquor industry has a virtual mandate from the public (i.e., the passage of Repeal) provides the rationalization that many of the regulatory codes (defined as holdovers from Prohibition) are superseded by the "higher law" of Repeal.

Although the frequency of criminogenic behaviors and their significance for the industry overall awaits further studies, field interviews found the assumption of such behaviors to be common talk among all levels. This produces a *callousness of attitude* which crosscuts all tiers and appears to be a factor in crimes of competition. The assumption that other participants have few scruples fosters the belief that survival in such an arena depends upon adoption of the same attitude. This belief becomes the *sine qua non* for the presence of criminogenic activity in any organizational complex.

Clearly, the opportunities to engage in

criminogenic activities are not problematic for the participants in the American liquor industry. Indeed, in large part, they structure the situations, engender the motive and produce the means which allow them to engage in such activities.

It is not clear whether governmental control of such substances as alcoholic beverages engenders the kinds of industry-initiated criminogenic activities observed in the several tiers of the liquor industry. Bribery, kickbacks, antitrust violations, payoffs and the circumvention of legal codes may or may not be specific to this industry. It awaits further case studies of an historical and observational nature to determine whether or not criminogenic conduct is basic to the survival, growth and success of American economic enterprises. Until such studies are available, we can only conclude with the following observation of a high-ranking official in one American distilling firm:

We break the laws everyday. If you think I go to bed at night worrying about it, you're crazy. Everybody breaks the law. The liquor laws are insane anyway. (field interview, August, 1975)

MULTIPLE ROLES AND ROLE STRAIN: SOME NOTES ON HUMAN ENERGY, TIME AND COMMITMENT *

STEPHEN R. MARKS

University of Maine, Orono

American Sociological Review 1977, Vol. 42 (December):921-936

Sociologists generally invoke a natural "scarcity" approach to human energy, stressing the overdemanding nature of multiple roles. In contrast, a seldom used "expansion" approach provides an energy-creation theory of multiple roles rather than a "spending" or "drain" theory. Empirical literature only partially supports the scarcity approach view that multiple roles inevitably create "strain." Moreover, human physiology implies that human activity produces as well as consumes energy. We need a comprehensive theory that explains both the scarcity and the abundance phenomenology of energy. Such a theory requires careful analytical distinctions between time, energy, and commitments. It is argued that particular types of commitment systems are responsible for whether or not strain will occur. A theory of scarcity excuses explains how strain or overload is generally rooted in one such system. Scarcity excuses get implicit support from scarcity theories, and a sociology of these theories suggests their ideological basis.

When sociologists theorize about multiple roles, they often appeal to some basic "stuff" of social interaction—a biological attribute called "energy." No one has critically analyzed the use of this concept or specified its concrete reference. It seems to be posited as a prime term that needs no further explication. I have found two principal images of this energy attribute, and for convenience they may be called the "scarcity" and "expansion" approaches. As most modern sociologists take the scarcity approach, I shall consider it first in some detail before turning to the much rarer "expansion" approach. Later, I shall consider two other concepts—time and commitments—and show how these have been so confused

with energy that it has been impossible to avoid bringing in all manner of ideological excess baggage in treatments of multiple roles.

The Scarcity Approach to Human Energy

Freud (1961) presented one of the clearest expressions of the scarcity approach, claiming that civilizations and lovers are enemies who jealously compete with one another for the individual's libido, or energy. Civilizations get built through energy that is borrowed from sexuality, energy that would otherwise be consumed in erotic or familial relationships. For Freud, since people do not have enough energy to be *both* good civilization-builders and good lovers, civilizations must block the various channels through which energy could flow unrestrictedly toward sexual objects. They accomplish this blockade by normatively prohibiting homosexuality, by restricting childhood sexuality, and by enforcing the norm of monogamous marriage. In this way, "civilization is obeying the laws of economic necessity, since a large amount of the psychical energy which it uses for its own purposes has to be withdrawn from sexuality" (Freud 1961:51).

Note that Freud writes here of an *eco-*

* Revised version of a paper originally presented at the annual meeting of the American Sociological Association, San Francisco, August, 1975. I wish to dedicate this paper to Kingsley Birge. For valuable feedback and/or encouragement at various stages, I wish to thank Joan Marks, James L. Spates, Linda Marks, Donald N. Levine, Daniel Ranalli, Elliot Cole and my colleagues at the University of Maine. I owe a special debt to Manfred Stanley, whose seminal paper on scarcity (1968) is a guiding though unmentioned influence throughout my own paper. Finally, I want to thank two anonymous referees and especially Morris Zelditch, Jr., whose very perceptive comments led to important refinements in a number of places.

nomic contest within the psyche. In so doing, he abandons any attempt to arrive at a substantive understanding of human energy and instead shifts our attention to the imagery suggested by a metaphor. This economic metaphor, which may be called the "spending theory" of human energy, is one of the two most common energy metaphors appealed to by modern social scientists, who seem to have borrowed it uncritically from the language of everyday life. There, we speak of energy in terms of supply and demand. It is said to be allocated to, and then consumed in this or that activity; it is spent or expended, invested or saved.

The other metaphor to which the scarcity theorists appeal is borrowed from the plumbing trade. It sees human beings as walking plumbing systems who have various outlets for their energies, which are said to flow through various channels and, finally, down various drains. This plumbing metaphor, which I shall call the "drain theory" of energy, is found not only in the language of everyday life, but, like the spending theory, it has been exploited by sociologists in formal discourse. Thus we find Bittner (1963:935) claiming that radical social organizations have to worry lest their members' energies "leak out" of their own organizations. And Coser stretches the metaphor to what must surely be its outermost limit, when he suggests that "all Utopian communities were concerned with channeling the emotional energies of their members into the brotherhood rather than letting them *dribble away* into private and exclusive channels" (Coser, 1974:140; *italics mine*). And logically, why not? If human energy can drain away, then why should it not be able to "leak"? Or "dribble"?

The spending and drain theories both typically see energy as a scarce quantity of natural "stuff" that is each individual's private possession. Both imply that it is used up every day in the sum total of daily activity. The drain theory assumes that our reservoir of energy is precariously small, something akin to a mud puddle that can readily drain away or dry up altogether. The spending theory likewise implies a tiny amount of energy that can be expended completely. It is as if we

begin the day with an energy "allowance," which we proceed to spend in our various activities, each costing us some of our allocation, until finally, having exhausted our resources by the end of the day, we fall asleep, receive our allowance for the next day and begin the cycle anew.

The Scarcity Approach: A Review of Some Theoretical Literature

The scarcity approach has been employed in a number of sociological settings, including general theory (see Moore, 1960:814) and social criticism (see Riesman, 1961:64). Most commonly, we are likely to find the scarcity approach as an adjunct to theorizing about the alleged difficulty of managing multiple roles. Moore's (1963:108) succinct claim is typical: "Given the scarcity of time and energy, the probability of role conflict for the multiple joiner is somewhat more than abstract and hypothetical." Note that Moore's scarcity claim is expressed not as a variable but as a pre-theoretical given, so no empirical evidence need be paraded about to support it. But note also the momentous theoretical consequences of this scarcity background assumption, for without it, the conflicts of multiple-role players either disappear altogether or else they must be assigned to other causative factors.

The linking of the scarcity approach with theories of multiple roles is best seen in three highly influential works: Goode (1960), Slater (1963) and Coser (1974). All three have proposed rather general theories, which others have often borrowed to theoretically ground a wide range of more specific empirical researchers.

Coser states in the first sentence of his recent book that

organized groups are always faced with the problem of how best to harness human energies to their purposes. . . . Competition for loyalty and commitment is a perennial problem because these are scarce resources. Not only do human beings possess only finite libidinal energies for cathecting social objects, but their resources of time are similarly limited. As a consequence, various groups having a claim on individual's

energies and time compete with one another in the effort to draw as much as they can, within normative limits, from the available pool of resources. The struggle over their allocation is as much a root fact of social life as is the competition of users of scarce resources in economic affairs. (Coser, 1974:1)

On this scarcity premise, Coser (1974:3) goes on to applaud "modern non-totalitarian societies," in which "people are expected to play many roles on many stages, thus parcelling out their available energies so that they can play many games." On the other hand, radical and millenarian social organizations come under attack because they are "greedy"; they demand *all* of the individual's time, energy and allegiance and thus tend to "devour the whole man" (Coser, 1974:18).

Goode is likewise concerned with the impact of all the claims made on multiple-role players. Unlike Coser, however, who argues that one's obligations in the modern, non-totalitarian world are underdemanding (relatively speaking), Goode (1960:485) argues that "the individual's total role obligations are *overdemanding*. . . . Role strain—difficulty in meeting given role demands—is therefore normal" (my emphasis). The individual's problem, therefore, "is how to allocate his energies and skills so as to reduce role strain to some bearable proportions." It is "the same problem," Goode (1960:487) adds, that "he faces in his economic life: he has limited resources to be allocated among alternative ends." And he solves this "problem" either by avoiding certain roles altogether or by making a series of "role bargains" in which his interest is to "demand as much as he can and perform as little" (Goode, 1960:495).

Slater, by a much different route arrives at a position similar to Goode's. His explicit starting point is a consideration of Freud's claim that civilization and lovers are antagonists who must compete for the individual's limited energy. In Slater's hands, Freud's thesis becomes generalized. The concept of civilization is replaced by the more generic "libidinal diffusion," which is *any* process of spreading out one's energy among a number of objects for a common purpose. And

Freud's concept of "lovers" gets replaced by "libidinal contraction," which is any process of restricting one's energy to a very narrow range of objects. Like Freud, Slater assumes an "inverse relationship between dyadic cathexis and societal cathexis: . . . If we assume a finite quantity of libido in every individual, then it follows that the greater the emotional involvement in the dyad, the greater will be the cathectic withdrawal from other objects" (Slater, 1963:343).

With Slater, then, one is led back to Goode's conclusion that the individual's total role obligations are overdemanding. People do not have enough energy for everyone, so some compromises must be made. Thus, for example, intense dyadic intimacy loses out to the interests of diffusion. "The [diffusion-oriented] marriage ritual then becomes a series of mechanisms for pulling the dyad apart." And later, "the marital partners are to a considerable extent drawn apart by their participation in same-sex groups in the community, particularly in the occupational sphere" (Slater, 1963:353, 357).

The Scarcity Approach: A Review of Some Empirical Literature

We have seen that the scarcity approach to human energy undergirds a number of rather general theories of multiple roles. These theories help set the stage for a sociologized version of the Hobbesian war of all against all: Each group in an individual's set of affiliations becomes the potential enemy of every other group, all warring for the individual's scarce time and energy. Role strain and role conflicts are thus inevitable and unavoidable, whether they are seen (with Goode) as difficult to manage or (with Coser) as not so difficult. Let us follow this scarcity perspective into a number of specific empirical researches dealing with multiple roles and see how it conditions the analysis.

Many studies of communes appear to be grounded in the scarcity approach. Kanter (1972:70), who summarizes much of this literature and who acknowledges both Slater and Coser, concludes that in stable utopian communes, "the person must in-

vest himself in the community rather than elsewhere and commit his resources and energy there, removing them from wherever else they may be invested." Citing Slater, she argues that stable nineteenth-century communes thwarted exclusive two-person sexual bonds and even close friendships among their members because these "represent competition for members' emotional energy and loyalty. The cement of solidarity must extend throughout the group" (Kanter, 1972:86). And again citing Slater, she notes a suppression of the nuclear family, since this institution can likewise threaten communal cohesion "by draining off emotional energy" (Kanter, 1972:89; for similar conclusions about communes, see Talmon, 1964; 1965; Zablocki, 1971:117, 225, 267; Coser, 1974:ch. 9).

There is apparent evidence that peer group solidarity is a consumer of people's energy both inside and outside the context of utopian communities. Slater (1963:349) claims that "strong opposition to dyadic intimacy is often found in youth groups which are formed on the basis of common interests. . . ." Bott (1971:279) sees a conflict between sex-graded peer groups and marital dyads, a conflict based on the "crude psychological assumption" that "there is a 'limited fund of sociability.' "

Nelson (1966) is one of many social scientists who has tested Bott's thesis. Nelson's data suggest that cliques "be considered as structural alternatives to the companionate family. It follows from the idea of a constant 'lump' or 'fund of sociability' that wives participating in cliques are less likely to make companionate demands on their husbands" (Nelson, 1966:668). When a wife with a companionate orientation to marriage *also* has frequent clique contacts, she "is confronted with competing and somewhat overburdening demands for her finite fund" (Nelson, 1966:670), and this claim also is apparently supported by Nelson's data.

Rainwater (1964), in discussing four "cultures of poverty," likewise sees a pattern of highly solitary, sex-graded networks and a rigid segregation of marital roles. His data point to a "low value placed on mutuality in sexual relations"

(Rainwater, 1964:463), a pattern which he sees as an extension of a low degree of marital intimacy generally. Rainwater (1964:464) adds that "it is possible that in such a system, a high degree of intimacy in the marital relationships would be antagonistic to the system since it might conflict with the demands of others in ego's network."

There is a wealth of empirical work dealing with the conflicts between occupational roles on one hand and familial and marital roles on the other, and this work is often grounded in a scarcity approach to human energy. Edgell (1970) concerns himself with "spiralist" professionals—people who combine a hierarchically-ordered career with residential mobility. Reviewing some of the empirical literature in this area, he summarizes as follows: "the spiralist at the child-rearing stage of the family cycle is faced with a dilemma: he can be 'married' to his work or his home and family" (Edgell, 1970:319). He adds that "the spiralist who attempts to subscribe to both influences" will be the victim of role conflict, "since any degree of commitment to one role will detract from his commitment, and chances of success, in the other, simply in terms of the availability of time and energy" (Edgell, 1970:320).

Cuber and Harroff's (1965: ch. 3) intensive interview data revealed an overabundance of "utilitarian" rather than "intrinsic" marriages. There were many more instances of "conflict-habituated," "devitalized" and "passive-congenial" marital relationships than there were "vital" or "total." These data seem to support the scarcity interpretation, since all the respondents were civilization-builders who should not have enough energy left over for intimacy and vital sexuality with their spouses (for similar conclusions about occupations and families that draw, at least implicitly, on the scarcity approach, see Dizard, 1968:55; Ridley, 1973:236; Rapoport and Rapoport, 1971:286–7).

The Scarcity Approach: Some Empirical Difficulties

The foregoing review of some theoretical and empirical literature necessarily has

been illustrative. My aim has been to show that any analysis of multiple roles can prompt the invocation of the scarcity perspective as soon as the analysis turns up even the *potential* for role conflicts or overload.

What happens when the analysis turns up some multiple-role players who do *not* appear to be struggling with role conflicts or suffering from role strain or overload? In many of the above-noted studies, while considerable empirical evidence is offered that multiple-role players tend to run out of time and energy, there is also evidence of a minority of each sample who do *not* seem to be experiencing the effects of scarce personal resources.

Thus, Nelson's (1966:668) data showed that 33% of the women with frequent clique contacts also made "companionate" rather than "traditional" demands on their husbands. Were they deliberately taxing their energy resources? And 35% of the women with both frequent clique contacts and companionate orientations to marriage were not apparently "overburdened" by their multiple roles and they did *not* express dissatisfaction with their husbands' understanding (Nelson 1966: 670).

Rainwater's (1964:461) data revealed that 20% of the "lower-lower"-class women were apparently *not* fully drained by their intensive kin and peer networks, as they made "very positive" statements about their enjoyment of sexuality with their husbands.

Dizard's (1968) study turned up minority instances in which high increases in the husband's income (allegedly reflecting increased occupational involvements) coincided with *increases* in the level of marriage adjustment, as reported by both husbands and wives, and there were many instances of such increases on every indicator of the marital adjustment scale used in that study (Dizard, 1968:55).

Cuber and Harroff's (1965) "vitality" married and "totally" married middle-aged couples also need to be explained. Like the couples with "utilitarian" marriages, they had extremely demanding careers, and yet they also turned out to be devoted companions and good and virile lovers. How are we to explain their appar-

ent abundance of energy, minority though they might be?

In short, if energy is seemingly abundant for some people, then we can no longer appeal to some universal human condition or natural fact to account for those instances in which it is found to be scarce. Therefore, we will need a more comprehensive theory than the naturalistic scarcity approach to explain why some people get into overload problems with multiple roles, while other people in the same settings do not.

These considerations suggested a sharper focus on how human energy functions generally. Both the spending and the drain metaphors imply that social activities always cost us a net loss of energy. To determine whether this is true we would have to know what this energy *is* that's being drained or spent, and what its source is. Unfortunately, sociologists seem to go no further than to qualify energy as psychic, as libidinal, or as emotional. Lowen (1971:18) argues convincingly that "if we are to avoid becoming mystical, we must regard the concept of energy as a physical phenomenon, that is, capable of being measured. We must also follow the physical law that all energy is interchangeable. . . . We work with the hypothesis that there is one fundamental energy in the human body whether it manifests itself in psychic phenomena or in somatic motion."

We might turn to physiology for some clarification. In living human cells, there is a universal energy molecule called adenosine triphosphate or ATP, which is converted from glucose. When muscle fibers contract (as they do in both physical and mental activity), they consume ATP. This consumption results in the conversion of more glucose into ATP, either from the glycogen reserves stored in the liver or, if the body is under greater stress, from body fat. The conversion process is facilitated by the release of adrenaline from the adrenal glands, but adrenaline release is best facilitated by muscle contractions and by a decrease in blood sugar owing to the using up of glucose. The circle is complete: the body stimulates the *production* of ATP from glucose only through the *consumption* of ATP in ac-

tivity; hence the process of production of human energy is inseparably a *part* of the consumption of energy. Activity is thus necessary to stabilize the production of human energy, and even while we are spending it we are also converting more of it for later use. (For a useful summary of this process, see Smith and Smith, 1973:39, 173-4, 235-6.)

It follows that the drain and spending perspectives on human activity are not supported by the facts of physiology, except when food intake is inadequate¹ or when the level of stress or exertion from activity is so great that not only the glycogen reserves are being exhausted but the bodily fat reserves are being used up faster than they can be converted. *Under all other conditions of daily activity, the energy potential of the body at any given moment is physiologically abundant rather than scarce.*

The Expansion Approach to Human Energy

Durkheim provided a sociological approach to human beings that could take note of the energy-producing element of social activity. "Life is not simply a precise arrangement of the budget of the individual or social organism, the reaction with the least possible expense to the outside stimulus, the careful balance between debit and credit. To live is above all things to act, to act without counting the cost and for the pleasure of acting" (Durkheim, 1953:86). Rather than human beings having to pay a price for their social involvements, Durkheim argued again and again, they come away from them far more enriched and vitalized than they are when left to their own "resources." "Sentiments born and developed in the group," he claimed, "have a greater energy than purely individual sentiments" (Durkheim, 1953:91; see also 1965:427).

Here, then, is an energy-expansion theory of activity and group life rather than a spending or a drain theory. It sees the available supply as abundant and ex-

pansible. Also, it focuses our attention on the energy attribute as a socio-culturally conditioned *variable* rather than as a biological fact of nature, thereby enabling us to ask important questions about its social production and not simply its consumption. Goode felt that when the family is pervaded by a sympathetic atmosphere, it uses up so little of the individual's energy that he has a lot left over for his more demanding roles (see Goode, 1960:493-4). But given the expansion approach, the possibility arises that family activities may *produce* more energy, precisely because of the sympathy therein. It is not that the family's freedom from the strict ranking of performances drains us less, but that any supportive and sympathetic atmosphere gives us more. In other words, perhaps some roles may be performed without any net energy loss at all; they may even *create* energy for use in that role or in other role performances.²

The Social Construction of Human Energy

I now had two rather different approaches to human energy. I could not deny the partial validity of the scarcity approach, as its draining and spending implications were not simply a figment of sociologists' imagination (witness Holmstrom's [1972:97] claim that "over half the professional women mentioned having problems, at least some time in their careers, of not having enough energy, of fatigue, of being tired and weary in a physical sense"). But neither could I impugn the partial validity of the expansion approach, as it seemed to offer an explanation of the gaps in the findings of those guided by a scarcity approach (witness Holmstrom's interviewees who did *not* mention problems of not having enough energy). In seeking a more comprehensive theoretical reformulation, I begin with the premise implied by human physiology: in terms of the reserves of

¹ To be sure, extreme malnutrition may create a chronic energy-drain for millions of the world's population.

² I know of scarcely any sociological treatments of multiple roles that work explicitly or implicitly with the expansion approach to human energy. Exceptions are an excellent paper by Sieber (1974) and Homans (1950).

energy for activity, human beings have abundant and perpetually renewing resources. The key questions for sociological theory then become (1) under what socio-cultural *conditions* does this energy potential become freely available for given activities and (2) under what socio-cultural conditions does it become unavailable? My thesis may be stated in the following four points:

(1) Rather than energy simply flowing out mechanically in response to everyone's demands until it runs out, persons *construct* their response to the demands of others. Thus, they implicitly *decide* how to use their energy and whose demands will be honored, if anyone's.

(2) People may *withhold* the full flow of their energy into a given role, thereby freeing that energy for engaging those role performances that are the most greedily demanded and heavily sanctioned or for embracing those that are simply the most valued culturally or personally. In this way it is possible for an individual with multiple roles to manipulate them so that only one of those roles gets the lion's share of his energy (cf. Coser, 1974, who seems to argue that through some miracle of social structure, multiple roles will automatically protect a person from being "absorbed" by a single role).

(3) If activity results in a feeling of energy loss, this situation is more a function of the variable *stance* of persons toward their activity-clusters and their role partners within them, rather than a simple matter of every role performance costing us some of our scarce biological resources.

(4) In the daily long run, we have ample energy for all of our role partners regardless of the other energy "expenditures" made earlier in the day. Abundant energy is "found" for anything to which we are highly committed, and we often feel more energetic after having done it; also, we tend to "find" little energy for anything to which we are uncommitted, and doing these things leaves us feeling spent, drained, or exhausted. With this perspective, let us return to multiple roles and the issue of why it is that some multiple-role players get into overload problems while others do not.

Time, Energy, and Commitment: Some Analytical Issues

Sociologists invoking the scarcity approach often have confounded time, energy, and commitment, treating them as if they are interchangeable scarce resources. Thus Coser begins his book by writing of competing claims on people's scarce *time* and *energy*, but "greedy institutions" are defined as ones that "seek exclusive and undivided *loyalty*" (Coser, 1974:4, my emphasis). This mixing of concepts does not create difficulties when analysis focuses only on the limiting cases in which total claims are made on a person's time and energy and commitments by a single social organization. The problems emerge only when we focus on those more common instances in which several social organizations and role partners make *conflicting* demands on a person's time, energy or commitment. In these cases, what is the "greedy" claimant demanding? More time, energy, commitment, or some combination? To say, as Coser (1974:2) does, that modern occupational demands on a person allow him sufficient free "time for his family or other non-occupational associations," is to say nothing of how he *uses* that free time, how he uses his energy in it, to whom he is committed (if anyone), or whether he even uses this possible free time non-occupationally (many people do bring briefcases home with them or voluntarily remain at the office after working hours). I may spend much time in the physical presence of my family, but use my energy for non-familial purposes during that time (e.g., by reading). Furthermore, my wife may press claims only on where I locate my use of time and not on my energy ("Can't you prepare for your class at home instead of at your office?"), or she may press for both my time and energy ("Can't we do something together tonight?").

The issue of commitment complicates the analysis much further. Indeed, an important empirical issue is to what extent increasing claims on a person's time and energy are really veiled complaints about the level of commitment of that person. In other words, some claimants may rest

content with having the unconditional *commitment* of other persons even while making few or no demands on their time and energy. Sieber (1974) points out that very small, occasional inputs of time and energy, especially in the form of dramatic displays, may be enough to demonstrate continued high commitment to certain role partners, who will be satisfied with that alone. On the other hand, some people who feel deprived of a role partner's commitment may still feel dissatisfied even if they are granted more inputs of time and energy from that role partner. Operationally, it could prove difficult to sort out what people really want from what they think or say they want, especially insofar as some people who claim to want more time and energy from a role partner may be psychologically protecting themselves from the knowledge of their partner's under-commitment to them.

These examples should suffice to show that there are, at the very least, three analytical variables involved in these issues—energy, time and commitments—and that it is essential to treat each of them as distinct from the others. Failing this, we have little chance of discovering when it is that multiple roles create strain or overload problems and when they do not. Our analysis of human energy has uncovered no naturally occurring deficiencies that can explain these problems. Let us consider time and then commitment.

There are some, like Moore (1963:4–11), who argue that time is naturally finite and scarce, and this view can serve those who argue that multiple roles necessarily give rise to strain. "Even if human energy is flexible and expansible," the argument would go, "there are only so many hours in the day, and time given here is time taken away there" (see, for example, Dizard, 1968:76).

To be sure, time may be *experienced* as scarce, particularly for North Americans, but this appears to be more a function of arbitrary cultural agreements and priorities than of some naturally occurring deficiency built into the human condition. Among the St. Lawrence Island Eskimos, "neither the concept of 'spending' as a process of transaction with an external agent nor the concept of 'time' as a dissec-

tible entity which can be used as the object of such a transaction has any validity. The cultural focus of daily activity is not on 'time' as a hollow shell which is to be filled with completed tasks or accomplished relaxation. Rather, the focus is on the *tasks* themselves which must be done" (Hughes, 1961:92, italics in the original). And the "tasks themselves" seem to include a full round of what we would call "leisure activities," although "the idea of time being 'set aside' for this purpose is unfamiliar" (Hughes 1961:93). If the scarcity of time is a universal human problem, these Eskimos apparently have not yet learned about it.

Given this consideration, a modified scarcity argument about time might go as follows: When social institutions in a complex society become segregated from each other (such as modern families and work-places), *then* time becomes experienced as universally scarce, since so many of one's activities will isolate one from so many of one's role partners to whom some time is owed." Note, however, that this formulation treats the experience of scarce time not as a *natural* occurrence but as a product of arbitrary socio-cultural arrangements. *If* place of work is distant from residence, then time may, of course, become a constraining resource. But to hold this situation as evidence that the human *condition* is constrained by scarce time is surely to beg too much, for it leaves unanswered the question of what the *priorities* were that led to places of work becoming distant from residences to begin with.

Moreover, even given the work/home segregations, there is still evidence of considerable variation in the way that time is structured and experienced within that framework, and some of these variations reveal an abundance of free time (which does not necessarily mean that people use it for any of their role partners). Komarovsky (1967:340–1) says of her blue-collar families that "there is no lack of togetherness in the sense of time spent in each other's physical presence," and that "shortening of the work day, smaller families, and the withdrawal of many economic functions from the home have given these couples long evenings and weekends

together." One study of 54 female elementary-school teachers has effectively treated as a variable "the number of hours an individual spends on work-related matters outside the working time formally required by the organization" (Gechman and Wiener, 1975:521-3). Not surprisingly, those who score higher on "job-involvement" tend to be the same ones who devote more "personal time" to work. Presumably, these individuals will tend to experience time as existing in shorter supply as well. Cuber and Harroff's (1965) respondents were all "top influentials" in their prestigious careers, but those who had "intrinsic" marriages seemed to arrange their lives so as to maximize time together as a couple, as evidenced by the man who "passed up two good promotions because one of them would have required some travelling and the other would have taken evening and weekend time" (Cuber and Harroff, 1965:56).

To be sure, people often have to work at making these kinds of accommodations, given the work/home segregation. The point to be made is only that time does not *present* itself to us as a prefabricated scarcity even in the modern setting. Like energy it is flexible, waxing abundant or scarce, slow or fast, expanded or contracted, depending upon very particular socio-cultural and personal circumstances. In short, we need to see the experience of both time and energy as *outcomes* or *products* of our role bargains, rather than assuming (like Goode) that they are already constituted for us as scarcities even before our role bargains are made.

Let us now consider commitment, the factor which I view to be the decisive one in whether or not some form of strain or overload will be experienced. I shall speak of a commitment when a person wants to carry out a more or less elastic cluster of performances over time, in light of his/her assessment of the importance of that cluster of performances. By "more or less elastic cluster of performances," I wish to emphasize the idea that most commitments point to a shifting number and range of rather ill-delineated *potential* performances, rather than to a set of ironclad and

numerically constant behaviors having clearly defined parameters which everyone knows. (The exception is ritualized performances.)

There may be any number of reasons why one wants to carry out a cluster of performances, why one thinks it is important to do so. Provisionally, I suggest four principal reasons, or elements of commitment: (1) spontaneous enjoyment of one or more of the specific performances in the cluster; (2) spontaneous loyalty to one or more role partners who want me to do it, or who will be pleased if I do it; (3) anticipation of some perceived reward, such as wealth, power, prestige, sympathy, approval, favorable self-image, etc.; (4) avoidance of perceived punishment, such as stigma, disapproval, status-loss, loss of rewards, etc.

Any one of these elements alone may generate commitment, although sheer enjoyment must surely be the quickest way to do so. At times the four elements may overlap, but at other times commitment may be maintained by virtue of only one of the elements being strongly present, even when the values of the other three elements would, by themselves, make for *non*-commitment. When all four elements independently and strongly support a given cluster of performances, the commitment level will be extremely high.

I suggest that commitments as here defined can be expanded indefinitely. This hardly implies that we can commit ourselves meaningfully to everything we can think of. It simply means that there is no inherent limit on the expansion of our commitment levels *within the scope of our own ongoing activities and the role partners we encounter within them*. Commitments are not governed by any natural scarcity principle that has yet been discovered outside the imagination of sociologists, and I postulate that increases in the entire range of our commitments are always possible. Whether any commitment *will* expand is a function of (1) any increase in value of one or more of the four elements of commitment or (2) any increase in the number of performances (within the cluster) that is assessed to be important. Further, any such increase would stimulate (1) increases in the sub-

jective energy level experienced during and after every interaction and (2) increases in the satisfaction with our role performances of every one of our role partners. Moreover, (3) the use of time will be found to be flexible enough to facilitate the above two changes, even to the point of accommodating additional units of time allowances to every one of our role partners. This last accommodation is always possible because of the creative strategies that human beings may adopt to "make time"—for example, compressing the time for certain activities through compactness or greater efficiency, doing two or more things at once, etc.

Systems of Commitments and Limits on the Expansion of Time and Energy

Without assuming an original condition of scarcity, how is it possible for overload (in the form of scarce energy or time) to occur as a regular phenomenon of human experience at all (disregarding those instances in which it occurs through situational crisis or urgency)? To say that high commitments expand energy and time while uncommitments contract these resources may be a good starting explanation, but it is insufficient. Many people are very highly committed to their jobs and devote enormous amounts of time and energy to them, but still feel they have more to do than they have time or energy for, as numerous studies (principally from the University of Michigan's Institute for Social Research) have shown (for a convenient summary, see French and Caplan, 1972). At the very least, these studies show that *sometimes* there are limits to how much energy and time can be expanded even by very high commitments.

To determine the nature of these limits, we first need to study the individual's total range of commitments as a system. That is, how do individuals assess the value or importance of a given role or activity-cluster in *relation* to their other roles and activity-clusters.³ Ideal-typically, the shape of this commitment system may

take three forms: (Type I) a system of equally positive commitments, in which anything one typically does is seen as just as good (worthy, important) as anything else one typically does; (Type II) a system of equally negative commitments, in which anything one typically does is seen as just as bad as anything else one typically does; and (Type III) a system of over- and under-commitments, in which one or more typical activities and roles are seen as better, more important, more worthy of one's efforts, etc., than any of one's other typical activity-clusters and roles. Note that a commitment in a Type I system and an over-commitment in a Type III system both have positive valences, and that the difference between them can be determined only by knowing the shape of the whole system of commitments to which they belong. Note also that in a Type III system, we do not see over- and under-commitments as positive and negative, respectively. Rather, *both* the over- and under-commitments occur on the plus side of a person's commitments. Both have positive valences, but the over-commitments have *higher* valences than the under-commitments.

It should now be apparent that Becker's (1960) conception of commitment is unacceptable for the present analysis. Becker sees commitment to entail the making of a series of "side bets" on a given line of activity, such that the expense of abandoning that line of activity would be too great. One has staked one or more originally extraneous interests on the continued performance of a given activity. Becker thus assumes a Type III system, because people's willingness to stake many of their extraneous valuables on a single line of activity implies that their *other* lines of activity (on which extraneous valuables have been staked) are seen as relatively expendable. Becker's "commitment," then, implies a system of over- and under-commitments, in my terms.

While individual systems of commitment may, of course, be rooted in personal idiosyncrasy, we are interested in the likelihood that such systems are *culturally* patterned for specific societies and for specific groups, classes, sexes and other social categories within societies. I

³ A very similar view has been taken recently by Gerson (1976:797-8).

suggest that in Type I cultures (whether societal or sub-societal), the phenomenon of scarce time and energy will be minimal. Equally high commitments to all of one's activity-clusters and role partners will maximize the production of energy and time for all of them.⁴ Here, what limits the expansion of energy and time for a given activity-cluster is the presence in one's total role and activity systems of other interests to which one is equally committed. And one's role partners will stand ready to release a person to his other interests, periodically because they, in turn, have their *own* outside interests which they will deem equally worthy of their energy and time. In brief, we might say that a natural "balancing act" is occurring here. Each of one's roles and activity-clusters will "swell"; each will become as elaborated as it can, within limits provided by the fact that all of one's other roles and activities will become likewise elaborated.

Type II cultures are probably limiting cases, as the absence of any positive commitments would generate diffuse apathy (see Aberle et al., 1950). Here, any expansion of energy and time is limited by the absence of any interest held to be worthy of one's efforts. The social production of energy is at a minimum. Empirically, the place to look for instances of this type would be within subcultures having a nihilistic, despairing or defeatist world view. Here, some time and energy are being produced, but only for the sake of the rejection of life, which, paradoxically, becomes a life-sustaining commitment.

Type III cultures surely constitute the most empirically common type, and the remainder of this paper will be devoted to analyzing their features. Concerning

under-commitments, the phenomenon of scarce time and energy should be very much in evidence. Here, what limits the expansion of time and energy is the omni-presence of one's over-commitments. No matter how much I might "value" my under-committed interests, my time and energy for them are always constrained by the fact that I have "better" or "more important" things to do.

Concerning over-committed interests, we should expect an enormous production of energy and time for them. Nevertheless, if some of my role partners are also over-committed to the cluster of activities in which I and they are commonly engaged, there may still be more to do than the already high production of time and energy can accommodate. Over-committed role partners will tend to expand their projects indefinitely, and since identity strength is likely to hinge much more on the success of these performances than on any others, no one involved in them is apt to release his/her role partners from doing their share of the work. Inevitably, then, over-commitments will lead to the swelling of the activity-cluster to which they are oriented; either the number of specific performances within the cluster will expand, or one or more of the performances within the cluster will become more elaborated, or both.

The tendency, then, is for over-committed interests sooner or later to begin to encroach on the time and energy being produced for one's under-committed interests.⁵ To cope with the demands of these swelling activity-clusters, over-committed people will want to contract their involvement in those activity-clusters to which they are under-committed. They may do this by decreasing the number of performances within them, by compressing them so that they require less attention and less elaboration, or by delegating others to do them. In

⁴ On the normative level, an empirical approximation of this type may be found in Zablocki's (1971) study of the Bruderhof, whose theology enjoins them to joyfully "bear witness" to the presence of the "holy spirit" in everything they do, no matter how commonplace. Zablocki (1971:31) suggests a parallel between this theology and Zen Buddhist teachings: "what they have in common is the desire to destroy the notion of a secular sphere of life. The message is that there are no activities, however trivial, that cannot be permeated by the divine spirit."

⁵ On the psychological level, over-committed interests will give rise to worry and anxiety, simply because the immensity of one's investment in these interests will lead to constant preoccupation with the performances associated with them.

turn, the *phenomenon* of scarce time and energy will become further heightened. As this happens, over-committed people will frequently need to give accounts to any role partners to whom they are under-committed.

Scarcity Accounts as Excuses

It is suggested here that when people are under-committed to a course of action or to a given role partner, they try to avoid being held accountable for their minimal or non-performances. To this end, they may be found appealing to a category of accounts called excuses, which Lyman and Scott (1970:114) define as "socially approved vocabularies for mitigating or relieving responsibilities when conduct is questioned."

My thesis in this connection is that popular appeals to the scarcity of time and especially of energy are tailor-made to serve as culturally honorable excuses for the under-committed. Scarce time may serve as an excuse for any person who is generally insulated from observability by a given role partner. ("I would have written, but I haven't had the time.") But scarce energy excuses can be advanced even failing this condition, because of the utter subjectivity and intangibility of the energy concept. That is, my energy level is a hidden entity, and even those role partners who can observe me full-time may have difficulty challenging my claim to a low level, so long as I am careful to refrain from any sign of vigor in my engagement of alternative activities.⁶

Scarce energy and time excuses are neither appealed to nor honored at random. Those who offer them and those who honor them do so by referring to very particular cultural priorities and standards of adequate role performance. I hypothesize that the cultural honorability of

these excuses will vary inversely with the level of cultural evaluation and rewarding of the activity-cluster within which the excuse is made. In the United States middle and upper classes, where occupational work is more highly valued and rewarded than any other activity-cluster, scarce time and energy excuses typically will not be honored within work activities, but they often will be honored outside the occupational arena. It is still probably true that a man who returns home from the "hard day of work" has the *right* to be too tired for further activities to which he is under-committed, unless his wife is a feminist who wants to modify the typical cultural agreements.

When culturally-favored roles (such as work) are themselves differentiated into a hierarchy of presumed importance, those people holding the highest positions will have the least latitude for scarce time and energy excuses within those positions (nor would they want to appeal to them), but they will also have enormous power of appeal to these excuses *outside* of those positions. A doctor cannot be too tired to attend to an emergency, but he probably can be too tired for a great variety of marital and family activities. On the other hand, for the traditional housewife, whose daily activities are not even reckoned culturally as real work, there is little power of appeal to any excuses.⁷

Sociological Ideology and Theories of Multiple Roles

When Coser, Slater, Goode and others claim that human energy, time, and even commitments are rooted in some inherent human condition of scarcity, they provide some unintended theoretical support for these scarcities as excuses. Insofar as they state this scarcity situation as fact without going through the usual procedures for garnering evidence, we must conclude that they are giving us ideology. But what ideology is it and why have they cast their lot with that side?

⁶ No duplicity need necessarily be charged to the layperson's appeal to these excuses. On the contrary, it is likely that under-commitment to an activity or role partner does indeed result in rapidly decelerating feelings of energy, even in the mere anticipation of that activity. Many of my under-committed students report that when they sit down to study, they not only feel little energy but often feel suddenly overwhelmed by the need to sleep.

⁷ As the Cosers (1974:92) point out, "power depends on resources, and women who do not have occupational resources are in a very poor position to share it equally with their husbands."

I shall turn once more to the work of Goode and Coser, as these sociologists have taken some pains to elaborate the postulates of their multiple-role theories. When Goode (1960:490) says that "some sort of overall value hierarchy seems to be accepted in every society," he apparently is postulating the universality of invidious distinctions between activity-clusters and between types of role partners, and, hence, the ubiquity of under- and over-commitments. At the same time, he recognizes that a given individual's role decisions will be greatly constrained by this "overall value hierarchy." This means, in effect, that individuals will be under pressure to direct their flow of performances to the more highly valued activities as their first priority—to those activities in which their performances are finely graded or ranked. They will be aided in this priority by the presence in their role system of "unranked or grossly ranked performance statuses" (such as family roles), which "permit the individual to give a higher proportion of his energy to the ranked performance statuses" (Goode, 1960:494). Clearly, as Goode (1960:493) points out, in Western society "it is mainly the occupational statuses" that are the most finely graded. Note that this means that, for Goode, the inevitable scarcity that he thinks plagues people's role resources will not tend to impinge on their performances and force them to make compromises until *after* the occupational roles have already been performed! If, indeed, it is "quite possible that what gets done is not enough," this possibility will surely actualize last in occupational activities. Thus Goode's theory postulates as normal the Western tendency to over-perform in occupations and under-perform in all other roles. If it is not for him inevitable that we choose occupational activities for our over-commitments, it is inevitable that we over-commit to something, since all societies make *some* invidious distinctions between activities. Hence, it might just as well be occupational activities as any others. In principle, then, Goode is ideologically on the side of anyone who, having over-committed to one set of activities, must struggle (more or less un-

successfully) to meet the "overdemanding" claims of all those other role partners left over in his total role system. In practice, however, since Goode is really talking about Western society, he has cast his lot with those who over-commit to their occupational roles and must then struggle with the consequences.

Like Goode, Coser is concerned with the individual's total role system, but we saw earlier that for Coser (1974:3), it is only "greedy institutions" that make one's total role system overdemanding; in contrast, modern non-totalitarian societies enable people to "parcel out their available energies so that they can play many games."

At first glance, it appears that the ideological intent of Coser's analysis is simply to bolster Western pluralism and individualism. He is on the side of those who, unencumbered by any monolithic greedy organization or role partner, can weave their way through a diversity of roles, making only partial commitments to each of their role partners, of whom no one is able fully to absorb them and drain their scarce time and energy. This ideological focus is reasonably secure when Coser centers his search for greediness outside contemporary Western societies. But Coser wanted to extend the scope of his theory, and he thus came to focus his search for greedy institutions *within* modern Western societies, which he earlier had exempted from the tendency toward greed. Accordingly, he turns (collaboratively with Rose Coser) to the modern nuclear family in terms of its greedy claims on the housewife. We learn that it is not the husband but the wife who "is expected to devote most of her time, as well as her emotional energies, to their family" (Coser, 1974:89). The ensuing analysis then focuses on many of the inequities that so many modern feminists have already brought to our attention. The status of the woman is determined by her husband (Coser, 1974:90). She tends to be excluded from the most prestigious occupational positions and, even when she gains entrance, she is still expected to shoulder most of the burdens of house-keeping and childrearing (Coser, 1974:90-2) which are not even reckoned as

"real work." And "it is she who bears the major burdens of residential uprooting and social dislocation" (Coser, 1974:97), occasioned by her husband's career mobility.

The Cosers treat the "greedy family" as a mere anomaly of modern life that will soon disappear. They "foresee a new family constellation in which both he and she are the family's providers, co-managers of the household and true partners in the care of their children" (Coser, 1974:100). What they fail to realize is that the greedy family for the woman is just the underside of the same coin whose top side is the greedy occupation for the man. They themselves claim that in American society, occupational status determines one's position in the stratification system and also one's power in the family, but they make no normative judgments about this situation; rather, they want the woman to increase her power by scaling up *her* occupational involvement to bring it up to par with the man's. But how could the woman scale up her occupational involvement without the man scaling down his own, since (in the Cosers' own analysis) it was the man's over-commitment to his occupation and his under-commitment to family activities that resulted in the family having a greedy hold on the woman to begin with? And how many men with prestigious positions will be motivated to scale down their investment in work, as long as one's position in the stratification system is determined by it alone, and family activities are defined as necessary "dirty work" and a waste of time?

Ideologically, then, Coser is on the same side as Goode; he has cast his lot with men who are over-committed to their occupational roles, and he holds up this over-commitment to women as well. While he argues that people with multiple roles can "navigate" among their "various obligations" (Coser, 1974:4), he knows that in practice Western people are first and foremost oriented to work; *after* work they struggle to navigate among all their remaining roles. Since in the process they often tend to experience a deficiency of time and energy, we are then given a

theory of *naturally* occurring scarcity to account for the deficiency.

The Sociology of Scarcity Approaches to Multiple Roles

Why do sociologists such as Goode and Coser offer us multiple-role theories that ideologically promote the over-commitment to occupational roles? To answer, we need only recall the one conclusion agreed upon by everyone who has studied the relationship between work and family life: strain, overload, and role conflict tend to be greatest for those who are most involved in, and oriented to success at work. Moreover, there is agreement that the class of professionals most often satisfies this condition of being oriented to occupational success. Sociologists are themselves professionals, and those who frequently publish and have widespread reputations are likely to rank highest on any scale of job involvement, orientation to success at work, and the like. Therefore, when these sociologists theorize about multiple roles it would be quite curious to find them somehow immune to their own personal realities, which have taught them that time and energy for pursuing interests other than their careers are perpetually scarce. In short, their ideological agenda is to pay homage to the occupational role because this has been found to be the greatest source of rewards in their own experience. Their unwitting support for scarce time and energy excuses, implicit in their appeals to a biological condition of scarce human energy, is hardly an invitation for people to be irresponsible. It is again an expression of their own personal realities, of the fact that time and energy do become experienced as scarce whenever people become over-committed to some of their activities and under-committed to others.

Note that the ideological support for occupations is also a reaffirmation of the existing system of social stratification, which, as the Cosers remind us, is *based* on the occupational division of labor. When the Cosers invite women to increase their occupational involvements, they are not proposing that women just go

out and get any job. Rather, they mean that they should go out and get enjoyable jobs—jobs that are highly prestigious and rewarding—jobs that rank high in the system of social stratification and that are, accordingly, scarce. Goode's support for the stratification system is more indirect but, by accepting the inevitability of a value *hierarchy*, he winds up supporting the system of stratification in the same implicit way that the functional theorists of stratification do.

Summary

In this paper I have argued that human resources of energy and time are flexible. They expand and contract, depending on very particular systems of commitment that determine their availability. I have suggested that scarce energy and time as *phenomena* (along with theories of role strain that ground these scarcities in some human condition) are specific to only one such system of commitments—a Type III system of over- and under-commitments. We need to know much more about all three types of commitment systems. What, for example, are the structural circumstances that foster the making of over-commitments? Presumably, any severe crisis situation will generate an over-commitment to resolve it, but extreme poverty may force people *chronically* to over-commit their resources to the activity of getting food and just "getting by." It may be that a modicum of affluence is a necessary (though not sufficient) condition for a Type I system of equally high commitments, thus suggesting that differences in individual commitment systems may have a socially stratified dimension. On the other hand, insofar as systems of social stratification are based on the notion that some activity-clusters are more important than others, it may be that Type I systems could only be typical in relatively strata-free societies. The answers to such queries must await further study.

CITY DIFFERENCES AND NONDIFFERENCES IN THE EFFECT OF RACE AND SEX ON OCCUPATIONAL DISTRIBUTION*

The Johns Hopkins University

American Sociological Review 1977, Vol. 42 (December):937-950

The empirical and theoretical analysis of intercity variation in black-white occupational differences constitutes a thin but persistent thread running through the last 30 years of sociological literature. At least nine separate statistical analyses have been reported in major sociological journals from 1951 to 1976, starting with Turner's (1951) attempt to test "some hypotheses frequently found in the race relations literature" concerning the relative occupational position of the Negro male in the labor forces of large American cities. This paper reassesses this entire literature on theoretical, methodological and empirical grounds. Our strategy here is to ask some key, underlying questions which never have been considered by earlier empirical studies of city differences in the race-occupation relationship. We find unexpected answers to these questions and these answers lead us to reexamine the dominant methodology of previous studies of the relative occupational standing of blacks and whites in U.S. metropolitan areas. In our methodological reexamination of earlier studies, we ask some additional basic, underlying questions which have not been considered in previous research, and the answers we find enable us to explain exactly how certain methodological conventions in this literature misled earlier researchers. As a further validation of our methodological arguments, and for theoretical reasons developed in this paper, we also investigate intermetropolitan variation in gender differences in occupational distribution. Finally, we draw upon recent theoretical and empirical research on the social evaluation of occupations to derive a theoretical explanation of why sexual differentiation and racial differentiation in the occupational structure does not vary substantially across U.S. metropolitan areas.

Research and Theory on Intercity Variation in Black-White Occupational Differences

Statistical study of intercity variation on occupational differences between white and black men starts with Turner's (1951) efforts to apply data from the 1940 U.S. Census of Population to some then-current ideas about race relations. Turner makes no specific citations of the theoretical literature which motivates his efforts, but we may reasonably infer from later attempts to extend his work that it is essentially the same body of writing that Williams (1947) synthesizes in his classic

volume, *The Reduction of Intergroup Tensions*. In that work, Williams suggests that hostility toward minority groups varies directly with (a) the rate at which the minority population increases in size relative to the non-minority population and (b) the ratio of the incoming population to the resident population. This hypothesis links the demography of the black population to the psychology of white Negrophobia and racial discrimination.

In order to investigate this and other hypotheses, Turner first constructed an "index of racial occupational equality" in each of 90 cities which had populations of 100,000 or more in 1940; he then measured the covariation between this index and certain other attributes of cities. Turner's findings were not entirely consistent with Williams' propositions, but by 1954, Allport had elevated Williams' remarks to the level of "a sociocultural law" (as

* Thanks to Robert M. Hauser for helpful comments, and to Susan Radius for research assistance during an early phase of this research. This work was supported by Grant 5 So5RR07041-09 from the National Institutes of Health, and by Grant 5T01MH11997-07 from the National Institute of Mental Health.

quoted by Blalock, 1956:227). Using methods similar to Turner's on 1950 Census data from the South and, separately, the non-South. Blalock (1956; 1957) produced findings which gave only ambiguous support, at most, to Williams' proposition. Glenn (1963; 1964) developed socioeconomic scores (SES) for major occupational groups and examined the relationship between black and white occupational SES in Standard Metropolitan Areas (SMAs) in 1950. For the non-South only, he finds a moderate negative correlation between the percentage of an SMA which is black and the SMA's ratio of black occupational status to white occupational status. He argues that where the percentage of blacks is large, blacks "overflow" into good occupations, thereby masking the effects of discrimination on racial differences in occupational attainment. Glenn (1963; 1964) also finds a positive correlation between white occupational status and the percent of the population which is black, leading him to argue that the white ability to exploit blacks varies directly with the percentage of the population which is black. Similarly, Cutright (1965) attempts to test the hypothesis that whites benefit from the presence of blacks in the labor force and presents correlations of about .98 between his index of white occupational benefit and the proportion of the experienced civilian labor force which is black in SMAs in 1950. Cutright reports similar results for 1960, and he finds no substantial differences when his analysis is restricted to the South or non-South, or to places with small or large black populations. Bahr and Gibbs (1967) make much of the high correlations they find between two measures of racial inequality and the index of dissimilarity (Delta) between the white and black male occupational distributions. Jiobu and Marshall (1971) estimate a path model which explains 80 percent of the variance in the index of dissimilarity between the white and nonwhite occupational distributions in 74 large urban places. Jiobu and Marshall's analysis is essentially an ecological and demographic analysis which stresses the role of a city's geographic location, black population growth, residential ghettoization, and industrial

composition in producing occupational differentiation between the races. Finally, Spilerman and Miller (1976) follow Spilerman's (1968) dissertation to develop a path model explaining Turner's index and several variations of it. Spilerman and Miller utilize 1960 U.S. Census Bureau data, and they stress the theoretical import of Turner's (1951) observation (confirmed by their analysis) that the Turner index is correlated with the proportion of a city's work force which is employed in manufacturing. Spilerman and Miller infer from this result that the pattern of ethno-racial organization in a city is affected by the structure of opportunities for socioeconomic attainment which are available to its residents.

If these studies of the city-race-occupation relationship tell us anything at all, they offer two basic conclusions. First, for about three decades, the sociological literature has indicated that *there is substantial intercity variation in the race-occupation relationship*. The assumed large size of city differences in this relationship has served as an implicit justification for testing hypotheses about, and building models of the relationship between a city's degree of racial occupational differentiation and its other characteristics. Second, one can conclude from past literature that *models and hypotheses which have been constructed to explain intercity variation in racial occupational differentials have been believed to have important implications for a wide variety of theoretical concerns, including (a) the social psychology of discrimination, (b) the relationship between the demography of the labor force and the structure of occupations and (c) the interrelations between industrial, occupational and ethno-racial patterns of social organization in contemporary America*. We now attack both of these conclusions on empirical, methodological and theoretical grounds. In a word, we find that variation in the race-occupation relationship between large metropolitan areas is trivial. We draw a number of general methodological inferences on the basis of our findings. We also search for intermetropolitan variation in the sex-occupation relationship. Consistent with our findings pertaining to

race, we find only trivial city differences in the sex-occupation relationship. However, we are able to apply some of the methodology which has been utilized to investigate intercity variation in the race-occupation relationship to "investigate" intercity variation in the sex-occupation association. This procedure provides us with an "interesting" but quite misleading causal model which is consistent with past findings pertaining to racial occupational differentials; thus, our analysis of sex differentials provides additional validation of some of our criticisms of past research on city differences in racial occupational differentials. Finally, we ask why urban areas should *not* be substantially different from each other with respect to racial and sexual occupational differentials. Our answer is theoretical and speculative, but it draws on a substantial body of recent empirical work on the social evaluation of occupations.

Measuring City Variation in the Race-Occupation Relationship

To assert that there is intercity variation in racial differences in occupational distribution is equivalent to asserting that the relationship between race and occupation varies across cities. Statistically speaking, that statement is an assertion that if one cross-tabulated workers' race by their occupation by their city of residence, one would observe a three-way interaction among these variables. If this race-city-occupation interaction were substantively insignificant in size, then it would be reasonable to conclude that intercity variation in occupational differences between the races is not sufficiently important to justify sustained empirical analysis of theoretical explanation. Thus, our present task is to measure the size of the city-race-occupation interaction.

To measure the size of the three-way interaction between city, occupation and race, we utilize published data from the 1970 U.S. Census of Population pertaining to the racial composition of the labor force in each of the 125 standard metropolitan statistical areas (SMSAs) which had a population of 250,000 or more persons at

the time of the census.¹ In the analysis immediately following, we utilize the Census Bureau's 12-group major occupation classification to represent the occupational distribution in each SMSA, and we use data on two racial groups only—blacks and whites. These data are arranged in a cross-tabulation of SMSA by race by occupation. To facilitate comparison of our findings to existing analyses by other researchers, our examination of racial data pertains only to males, and we perform separate analyses for the South and non-South.

In order to measure the size of the three-way interaction between SMSA, occupation and race, we apply log-linear techniques for the analysis of cross-classifications developed recently by Goodman and others (see Bishop et al., 1975). We use the widely available Goodman-Fay computer program, ECTA. These methods allow one to fit various models to a cross-tabulation and to generate measures of how well the model fits the observed data. A model in this context is merely a statement of which possible relationships among the cross-tabulated variables are actually present in the data. If a model which does not include the triple interaction fits the data very well, then we can safely infer that city differences in the race-occupation relationship are not, on the average, large. We use two complementary methods to determine how well a log-linear model fits the observed frequencies in the table. The first method is based on the percent of cases misclassified by a model; the second method is based on chi-square statistics. To apply the first method, we fit a model to the data which allows different numbers of persons in each SMSA, different numbers of persons in each racial category, different

¹ Tabulations used in this paper are published in U.S. Bureau of the Census, 1973. Data for this tabulation were taken from the 20 percent sample of population by the Census Bureau, but published figures have been inflated to yield estimates of population values. To deflate these figures to approximate sample values, we divided them by five before analysis. Necessary data are not published for SMSAs with populations less than 250,000 persons. For convenience only, we treat the terms "SMSA" and "city" as synonymous words throughout this paper.

numbers of persons in each occupation, *and* the three pair-wise relationships between SMSA, race and occupation. Since this model does not allow an SMSA-race-occupation interaction, it forces the race-occupation relationship to be the same in all SMSAs. If the relationship varies substantially across SMSAs, the model will misclassify many cases. We have calculated that this model misclassifies only 1.1 percent of the cases in the non-South and 1.9 percent of the cases in the South—a spectacularly good fit. Calculating the percent of misclassifications separately by race, we find that 0.6 percent of the nonsouthern whites are misclassified, and 1.1 percent of whites in the South are misclassified; 6.3 percent of nonsouthern blacks are misclassified, and 6.0 percent of blacks are misclassified in the South. Thus, we find that city differences in the race-occupation relationship have only minute effects on the occupational distribution of whites and very minor effects on the occupational distribution of blacks. (The reader should bear in mind that misclassifications can be caused by the effects of variation in employment patterns, clerical errors in data handling and sampling variability—percentages misclassified give high estimates of the importance of the three-way interaction.) Indeed, if city differences in the race-occupation relationship are ignored completely, we can fill out the SMSA-race-occupation cross-classification with 99 percent accuracy in the non-South and 98 percent accuracy in the South, using only the two-way marginals of the three-variable table to guide us.

Our second method for determining the importance of the SMSA-race-occupation interaction is based on chi-square statistics. The chi-square statistic for a given model can be regarded as the amount of association which remains in the cross-tabulation *after* the model has been fitted; one can compare chi-square values for different models to measure the importance of interaction effects in much the same way that one uses the analysis of covariance to measure the importance of adding interaction effects to a regression model (see Goodman, 1972 for amplification of the analogy between his methods

and least-squares procedures for estimating variance components; Hauser et al., 1975 provide a careful empirical application of Goodman's techniques for decomposing the association in cross-tabulations). We use chi-square statistics in the following way to calculate the importance of the SMSA-race-occupation interaction. First, we fit a model which allows different numbers of persons in each city, different numbers of persons in each occupation and different numbers of persons in each racial category, but no relationships between these variables. Thus, the chi-square for this first model (CS_1) is attributable to the relationships which are *not* included in the model: the three pair-wise relationships between race, SMSA and occupation, and the triple interaction between these three variables. In the second model, we allow different numbers of persons in each city, different numbers of persons in each racial category, different numbers of persons in each occupation *and* the three pair-wise relationships between race, SMSA and occupation. The only relationship that is excluded from the second model is the triple interaction. Consequently, the chi-square statistic for the second model (CS_2) indicates the amount of the association which is attributable uniquely to this three-way relationship. In common language terms, the chi-square for the second model indicates the amount of association due to SMSA differences in the relationship between race and occupation.

In order to judge the size of the chi-square statistic for the triple interaction (the second model), we compare it to the chi-square statistic for the first model. This procedure allows us to express the association due to the triple interaction as a fraction of the association in the table which is due to all relationships between race, occupation and SMSA, including the three-way relationship (when comparing CS_2 to CS_1).

Table 1 gives the chi-square values when the two models are fitted to data on southern SMSAs only, and data on SMSAs on the non-South, following previous analyses. Looking at column A of Table 1, notice that in the South the chi-square for the first model is 274,809.6 and

Table 1. Chi-Square Statistics, Degrees of Freedom and Ratios of Chi-Squares for Analyses of SMSA-Race-Occupation Cross-Tabulations, for the South and the Non-South

Model	Likelihood Ratio Chi-Square Statistics	
	South A	Non-South B
1. (Race), (Occupation), (SMSA)	274,809.6 (954)	555,464.4 (1,897)
2. (Race, Occupation), (Race, SMSA), (SMSA, Occupation)	8,436.5 (451)	11,625.7 (902)
3. (Race, SMSA), (SMSA, Occupation)	165,609.2 (462)	166,286.5 (913)
Ratios of Chi-Squares		
CS ₂ /CS ₁	3.1%	2.1%
CS ₃ /CS ₁	5.1%	7.0%
Number of SMSAs	42	83

Notes: (a) Degrees of freedom shown in parentheses below corresponding chi-square statistics.

(b) Regional definitions are those of the Census Bureau.

(c) These models are hierarchical. Thus, models 2 and 3 specify the three one-way marginals as well as the pair-wise relationships which are indicated.

the chi-square for the second model is 8,436.5. *In proportional terms, this indicates that the triple interaction is only 3.1 percent of the association between race, occupation and SMSA in the South, and only 2.1 percent in the non-South.*

Leaving aside questions of statistical significance for the moment, it seems appropriate to ask if two or three percent is a substantial amount of the association in the race-occupation-SMSA cross-tabulation. We think that these percentages are not substantial, and we suspect that few persons would consider an equivalent amount of any measure of association worthy of sustained substantive interpretation. *So we think that the data give no reason to believe that much effort should be spent attempting to explain city differences in the race-occupation relationship.*

However, we can be more generous to the argument that there are large city differences in the race-occupation relationship if we are willing to accept the position that the race-SMSA association and the occupation-SMSA association are irrelevant to present concerns and, therefore, should not be included in the denominator of the ratio which is used to calculate the proportion of association which is at-

tributable to the three-way interaction. We can think of a good reason for *not* accepting that position,² but there is no point in arguing the matter, since we can show that even if one were to accept it, the empirical results would still support our contention that the SMSA-race-occupation interaction is small enough to be considered inconsequential.

In order to subtract the chi-square due to the association between race and SMSA and occupation, we specify a third model which allows for the observed univariate distributions of race, SMSA and occupation, and which also allows for the observed bivariate relationships between SMSA and occupation and between SMSA and race. The only relationships which are not specified by this model are the relationship between race and occupation and the SMSA-race-occupation triple interaction. Thus, the chi-square statistic for model three indicates the association which is due to the combined effects of the "main" relationship between race and oc-

² This position is analogous to arguing that in the analysis of covariance one should not allow for additive effects of the subclasses before estimating the importance of the interactions between regressors and subclasses.

cupation and the additional association which appears when the race-occupation relationship is allowed to vary across SMSAs. The chi-square statistics for this model are shown in the row of Table 1 corresponding to the third model.

Looking at the row in Table 1 corresponding to model three, notice that for the South, the combined effects of the race-occupation association and the SMSA-race-occupation interaction produce a chi-square of 165,609.2. For the non-South, it is 166,286.5. We now use these figures as a standard of comparison in evaluating the size of the chi-square attributable to the triple interaction alone. Looking at the appropriate row of Table 1, notice that the interaction amounts to 5.1 percent of the association in the South, and 7.0 percent in the non-South. Once again, it does not seem to us that these results are consistent with the belief that city differences in the race-occupation relationship are important and worthy of sustained theoretical and empirical analysis.

Before going on to gender differences in occupational distribution, two issues need brief attention. First, the SMSA-race-occupation interaction is statistically significant, in spite of its substantive unimportance. However, statistical signifi-

cance is a reflection of the extraordinary sample size (over 9.9 million data cases) rather than the strength of the relationship. Second, it is crucial to understand that we are *not* attacking the use of "city" as an independent variable on the ground that it does not explain much variance. Rather, we argue that intercity variation in the race-occupation relationship makes a poor *dependent* variable because it has so little variance to be explained.

Intercity Variation in Sex Differences in Occupational Distribution

Race is not the only basis for social differentiation in the labor market; women have also suffered from occupational discrimination, and we have utilized Census data on sex differences in occupational distributions to measure the strength of the SMSA-sex-occupation interaction in 1970. Column A of Table 2 provides the results of an analysis which is analogous to the analysis of city differences in the race-occupation relationship shown in column A of Table 1. Looking at column A of Table 2, notice that the triple interaction amounts to a trivial 2.5 percent of the association in the sex-occupation-SMSA cross-tabulation after allowing for all the observed univariate marginals of the sex,

Table 2. Chi-Square Statistics and Degrees of Freedom for Analyses of Sex-Occupation-SMSA Cross-Tabulations, 1970

Model	Likelihood Ratio Chi-Square Statistics	
	125 SMSAs and 12 Major Occupation Groups A	9 SMSAs and 125 Detailed Occupation Categories B
1. (Sex), (Occupation), (SMSA)	3,296,797.6 (2,863)	103,704.8 (2,116)
2. (Sex, Occupation), (Sex, SMSA), (Occupation, SMSA)	82,977.0 (1,364)	3,257.0 (992)
3. (Sex, Occupation), (Sex, SMSA)	2,885,919.4 (1,375)	87,617.1 (1,116)
CS ₂ /CS ₁	2.5%	3.1%
CS ₂ /CS ₃	2.9%	3.7%

SMSA and occupation distributions. After allowing for the univariate marginals and the sex-SMSA and occupation-SMSA relationships, the interaction accounts for 2.9 percent of the association. These findings are entirely consistent with our results concerning city differences in the race-occupation relationship.

Although all earlier analyses of SMSA differences in relationships between minority status and occupation that we know of have been based on analyses of major occupation groups only, occupations within these major groups are so heterogeneous that city differences in the sex-occupation relationship might be masked by the grossness of the major occupation categories. Ideally, one would test this possibility by using the 417-category Census detailed occupational classification instead of the 12-category major occupation group classification. But use of the detailed classification was beyond our computational resources when we undertook this research, and so we drew a stratified random sample of 125 1970 detailed occupational categories and a stratified random sample of nine SMSAs of population greater than 250,000 persons.³ We have performed another

analysis of the cross-classification of sex by these 125 occupations by the nine sampled SMSAs. The results of the analysis are shown in column B of Table 3. Notice that the results in column B are consistent with all the other analyses we have performed so far: the triple interaction amounts to only 3.1 percent of the total association after allowing for the one-way marginals.

Replicating Past Findings with 1970 Data

However convincing we have been in arguing that there are no strong city-race-occupation and city-sex-occupation interactions in the 1970 Census data that we have analyzed, it is still possible that these relationships existed prior to 1970 (when the earlier studies cited above were done). Thus, we may have merely discovered that city differences in the race-occupation and sex-occupation relationships disappeared from 1960 to 1970, rather than showing that earlier analyses were incorrect. We doubt that improvement in black occupational status was sufficiently large to make this possibility even plausible, but we consider it all the same. In order to test this possibility, we use the data from our analysis to estimate the coefficients of Spilerman and Miller's model.⁴ If we find the same results with the 1970 data that they found with the 1960 data, then we can be reasonably sure that it is not their data but their method that leads them to different conclusions than our own. Also, since Spilerman and Miller takes pains to establish the comparability of their analyses with those of earlier re-

³ The universe for the sample of occupations was the set of 485 detailed occupation titles in the 1970 U.S. Bureau of the Census expanded occupational classification system. A stratified probability sample was drawn in order to allow particular attention to be given to (a) occupations having relatively high proportions of females in their labor force, (b) professional and managerial occupations and (c) occupations having relatively high proportions of blacks in their labor force. These criteria defined three overlapping subsets of occupations and a residual set of occupation titles which were not included in the three strata:

- (1) Occupations with relatively high (20% or more) proportions of black incumbents;
- (2) Occupations with relatively high (80% or more) proportions of female incumbents;
- (3) Occupations included in the major occupation categories, Managers and Administrators, and Professional and Technical;
- (4) All occupations not included in the above.

Occupations included in more than one stratum could be selected more than once, and their sample weights were adjusted accordingly. However, sample weights were ignored in the log-linear analyses, as were strata, and no occupation appeared more than once in the analyses presented here. Thus, the sampling design merely assured that the analysis gave good "coverage" to occupations in which

minority employment (the subject of this paper) has been most problematic, while allowing all occupation titles to enter into the analysis. Sampled occupations are listed in Stolzenberg and D'Amico (1976).

The sample of SMSAs is composed of eight randomly chosen SMSAs and one self-representing unit which was included in the sample with unit probability. The eight random SMSAs are Erie, Pa.; Denver, Co.; Rockford, Ill.; Lansing, Mi.; Salt Lake City, Ut.; Springfield, Ma. (and nearby Ct.); Atlanta, Ga.; Austin, Tx. The self-representing SMSA is Baltimore, Md.

⁴ At the time this paper was written, the Spilerman-Miller article was scheduled to appear in the August issue of the ASR but publication has been delayed.

Note: * Difference between 1970 coefficient and 1960 coefficient is more than 1.96 times the value of the standard error of the 1970 coefficient.

searchers, demonstration of comparability between our work and Spilerman and Miller's also will help establish the comparability of our findings to earlier studies based on the Censuses of 1940 and 1950. And, finally, a detailed replication of earlier work based on Turner's index will enable us to diagnose the features of earlier work which led to conclusions other than our own.

Spilerman and Miller's empirical analysis is essentially a refinement, elaboration and synthesis of previous statistical studies of intercity variation in occupational differences between white and black men. That is, they use Turner's index (and several variants of it) to measure occupational differentiation between the races in metropolitan areas, but, unlike other users of this index, they develop a causal model similar to that of Jobu and Marshall (1971) to explain the variation in it. Turner's index is the ratio of the percent of nonwhites in "good" occupations divided by the percent of whites in "good" occupations. Turner defined good occupations as those major occupation categories which are "semi-skilled and

higher" (i.e., occupation groups other than "farm and nonfarm labor, domestic and other service work"; see Turner, 1951:524 or Spilerman and Miller, 1976, for details). The core of Spilerman and Miller's analysis is a pair of regression equations, one predicting the numerator of this index and the other predicting its denominator. Table 3 gives the coefficients of the six variables in the Spilerman-Miller model estimated from 1960 data by Spilerman and Miller, and our estimates of the coefficients of the same variables for 1970.⁵ In Table 3,

⁵ Spilerman and Miller excluded SMSAs with fewer than 3,500 nonwhites and "SMSAs in which blacks comprise less than 90 percent of the nonwhite population." We also deleted SMSAs with fewer than 3,500 nonwhites, but we mistakenly also deleted SMSAs in which blacks comprise less than 90 percent of the nonwhite male ECLF (rather than 90 percent of the nonwhite population as a whole). The effect of this difference between our exclusion criteria and Spilerman and Miller's is obviously trivial. We remind the reader that our analysis is based on SMSAs larger than 250,000 persons, while Spilerman and Miller's analysis is based on SMSAs larger than 100,000 persons. Our analysis excludes nonblack nonwhites.

notice that the coefficients for 1960 and 1970 are generally quite similar. For a more formal test of the similarity between the Spilerman and Miller findings and our own, we can assume that their coefficients are "true" and then test the null hypotheses that each of our coefficient estimates differs significantly from theirs.⁶ Coefficient estimates from our analyses which differ from Spilerman and Miller's by more than 1.96 standard errors (indicating a confidence level of five percent for a two-tailed test) are marked with an asterisk in Table 3. Looking at Table 3, notice that only 2 of the 12 coefficients differ at the five percent confidence level: there is not much difference between the results that Spilerman and Miller obtained using 1960 data and the results we obtain replicating their analysis with 1970 data. Thus, it seems very doubtful that Spilerman and Miller would have drawn different conclusions if they had used the same data base that we utilize in our log-linear analyses of contingency tables. Further, we re-did our log-linear analyses after excluding certain types of cities that Spilerman and Miller deleted from their analysis of 1960 data (see fn. 4). Results of this additional analysis are entirely consistent with all of our other findings in this paper.

Thus, our data are quite comparable with those of Spilerman and Miller and, therefore, with those used by earlier analysts. But how do we reconcile the gross differences between our conclusions and theirs? We think that the answer to this question is that the specification used in virtually all analyses of the Turner index hides the association between the components of the index, thereby confusing a straightforward set of relationships. That is, all studies that we know of which utilize the Turner index examine the hypothesized causes of the index, or the determinants of its various components,

but none considers the relationship among the components of the index itself. We have computed the correlations among the four components of the log of the Turner index.⁷ These correlations are all larger than .92. The correlations between the log size of the white male ECLF and the log of the number of white males who are in "good" occupations is .99977, indicating that the number of white men in "good" occupations in an SMSA can be determined almost exactly from the number of white males in the labor force of the SMSA. Similarly, a correlation of .99847 indicates that the number of black men in "good" occupations in an SMSA can be predicted almost exactly from the number of black males in the ECLF of the SMSA. Thus, once one knows the number of white men and the number of black men in the ECLF of an SMSA, all the components of the Turner index are also known. In plain English, this means that city differences in the race-occupation relationship are so small that one can accurately calculate the Turner index for an SMSA merely by knowing the numbers of white and black men in the SMSA's labor force. Thus, the same conclusions that we draw from our log-linear analyses of city-race-occupation cross-tabulations could have been drawn by examination of the correlations among the index components.

Some further illustration of the shortcomings of the Turner index are vividly illustrated by assuming for a moment that it is a valid indicator of minority-nonminority occupational differences. Making this assumption, we follow Turner's (1951) and Spilerman and Miller's (1976) earlier conclusions that the industrial composition of a city partially

⁶ The assumption that regression estimates are without error makes these tests generous to the hypothesis that the coefficients are different. If we assume that the standard errors for the Spilerman-Miller coefficients are the same as those of the corresponding numbers in our replication, then only the coefficient for the percent of the SMSA which is Negro (in the equation for the denominator) differs across the two years.

⁷ Spilerman and Miller examine the relationship between the index and its components, but they do not scrutinize the relationships among the components themselves. The correlations we computed are as follows: where $x_1 = \log(\text{number of white males in "good" occupations})$, $x_2 = \log(\text{number of black males in "good" occupations})$, $x_3 = \log(\text{number of white males in ECLF of SMSA})$, and $x_4 = \log(\text{number of black males in ECLF of SMSA})$, $r_{1,2} = .92518$, $r_{1,3} = .99977$, $r_{1,4} = .93126$, $r_{2,3} = .92189$, $r_{2,4} = .99847$, and $r_{3,4} = .92840$. (These correlations were computed on 1970 data on non-South SMSAs of 250,000 or more residents which meet Spilerman and Miller's criteria for inclusion in their data base.)

Table 4. An "Interesting" Analysis of City Differences in the Occupational Standing of Women Relative to Men, Using the Log of the Turner Index as the Dependent Variable *

Independent Variable ^b	Standardized Coefficient
Proportion employed in agriculture, forestry and fisheries	.149
Proportion employed in mining	-.211
Proportion employed in construction	-.192
Proportion employed in durable goods mfg.	-.988
Proportion employed in nondurable goods mfg.	-.439
Proportion employed in non-specified mfg.	.295
Proportion employed in transportation, communications and other public utilities	-.076
Proportion employed in wholesale trade	-.264
Proportion employed in retail trade	-.396
Proportion employed in finance, insurance and real estate	.091
Proportion employed in personal services	-.820
Proportion employed in entertainment and recreational services	.663
Proportion employed in professional and related services	-.263
Proportion employed in public administration	-.107
Number of persons in experienced civilian labor force	.011

- Notes: (a) Dependent variable is the natural logarithm of the ratio of the proportion of female labor force participants who are in "good" occupations divided by the proportion of male labor force participants who are in "good" occupations. "Good" occupations are those occupations which are not included in the 1970 Census major occupation categories Laborers, Service workers except private household, and Private Household workers.
- (b) Natural logarithms of all independent variables were taken before performing calculations. These independent variables are proportions of the total experienced civilian labor force that are employed in the various industry groups. Since the log of these variables is used, the number of persons in the ECLF of the city is an additive component of each of the log-ratios. The confounding effect of this common component is held constant by including the logarithm of the number of persons in the ECLF as an independent variable in the regressions.
- (c) For computational procedures and multiple correlation coefficients, see footnotes to the text.
- (d) The industry category "Industry not reported" was excluded from the list of independent variables to avoid redundancy; persons not reporting their industry were included in the number of persons in the experienced civilian labor force.

"causes" the occupational differentiation between minority and nonminority members of its labor force. We then compute the Turner index for sexual differences in occupational distribution for 125 SMSAs using 1970 Census data described earlier and Turner's original distinction between "good" and "less good" occupations. In order to estimate the effects of an SMSA's industrial composition on its occupational differentiation between the races, we then regress the log of the Turner index on the percent of its labor force in each of 14 major industrial categories (the 15th category would be redundant, making the equation impossible to estimate, and is left out of the regression). We hold city size effects constant by including in the regression the log of the size of the experienced civilian labor force (ECLF) in the SMSA. The results of the analysis are shown in

Table 4.⁸ Looking at Table 4, notice that the standardized coefficients for several industry categories are substantial, suggesting that the sex-occupation relationship varies substantially according to the industrial composition of an SMSA. However, we have already shown that the sex-occupation relationship does not vary very much across SMSAs, and so these

⁸ Following Spilerman and Miller, we calculated separate equations for the logarithms of each of the four components of the Turner index. The logs of the numerator and denominator of a ratio are additive components of the log of the ratio, making it possible to use coefficients from these equations to compute the effects presented in Table 4. The R-squared statistics for the four equations are as follows: for the equation for the log number of women in "good" occupations, .5178; for the equation for the log number of women in the ECLF, .4899; for the log number of men in "good" jobs, .14878; and for the log number of men in the ECLF, .4753.

regressions merely serve to illustrate the misleading nature of the Turner index.

By this point, the dangers of using the Turner index seem well established. But readers will recall that two earlier studies (Jiobu and Marshall, 1971; Bahr and Gibbs, 1967) utilized the well-known index of dissimilarity (Delta), rather than Turner's index to measure occupational differentiation between the races in metropolitan areas. Although these authors do not give much substantive consideration to the amount of variation in Delta across SMSAs, it is clear that the measure's standard deviation is far from negligible in both analyses.⁹ Given that Delta has been widely used in studies of racial occupational differences (see, for example, Siegel's [1965] classic paper) and in studies of city differences in residential segregation (see, for example, the benchmark study by Taeuber and Taeuber, 1969), it seems important to determine precisely how Delta could vary substantially across cities when the race-occupation relationship does not.

The reason that Delta varies while the race-occupation relationship remains stable is that Delta is sensitive to the marginals of the race-occupation cross-tabulation. To see this, imagine an uncomplicated occupational structure with only five occupations. Also imagine a simple form of racial discrimination in which there are quotas which limit the proportion of blacks in the labor force in each occupation. Further, imagine that these quotas are more restrictive in some occupations than others, that there are fewer blacks than whites in the labor force, and that job-related skills and abilities are uncorrelated with race. Assume also that the racial quotas for the five occupations are as follows (the numbers chosen here are arbitrary, and others will do as well): occupation I, 20 percent black; occupation II, 30 percent black;

occupation III, 40 percent black; occupation IV, 50 percent black; and occupation V, 60 percent black. Now imagine two cities, "A" and "B," with different occupational structures such that city "A" has 200 white incumbents of each of the five occupations, and city "B" has 50 white incumbents of occupation I, 100 white incumbents of occupation II, 200 white incumbents of occupation III, 400 white incumbents of occupation IV, and 800 white incumbents of occupation V. Clearly, the race-occupation relationship in the two cities is the same, since the racial quotas are the same. But the index of dissimilarity has a value of 15 in the first city and a value of 8.35 in city "B." Thus, Delta quite clearly depends upon *both* the marginal distribution of the occupational structure *and* racial inequality in job opportunities. Fortunately, the log-linear analyses that we use in analyzing city differences in the race-occupation relationship explicitly differentiate between effects of marginal distributions and effects of the race-occupation relationship.

Conclusions

Using log-linear methods, we have shown that the race-occupation relationship varies only trivially across U.S. metropolitan areas in 1970. We have shown that the 1970 data is comparable to data from earlier years, supporting the view that large city differences in this relationship did not exist in any of the years in which it has been analyzed. We then re-examined the methods used by earlier analysts, and we were able to show precisely how these techniques produced misleading statistical results and led to incorrect inferences about city "differences" in occupational differentiation between the races. We also were able to show that the sex-occupation relationship does not vary substantially across large metropolitan areas, and we demonstrated how application of certain methods used by other analysts would lead one to infer that such differences are real and that they are theoretically interesting.

But, in spite of the heavy methodological and empirical orientation of this

⁹ Jiobu and Marshall (1971:644) find a standard deviation of 10.58, as compared to a mean of 41.33. We calculated the mean and standard deviation from data shown in Bahr and Gibbs' Table 1: for the 33 SMSAs for which they calculated Delta, the mean is 51.51 and the standard deviation is 8.47.

paper, the major conclusions that we wish to draw are theoretical, and a return to theory seems an appropriate ending. We begin by stressing that we have *not* found that all cities are alike. Our analyses have been concerned with overall measures of city variation in racial occupational differentials, and we have found that such variation is, in general, small. But we have not found that all *pairs* of cities are identical in this respect. Dallas may be a lot better for black men than Hoboken, for example, but the average difference between the race-occupation relationships in randomly chosen pairs of cities is small. Thus, while persons with a particular interest in a specific city may reasonably consider the (possibly large) anomalies in that city's race-occupation relationship, cities do not, in general, depart from the norm sufficiently to justify the substantial effort that has been expended in understanding intercity variation in racial occupational differentials.

We also remind the reader that our analyses in this paper have been confined to SMSAs of 250,000 persons or more. Thus, we cannot positively eliminate the possibility that our conclusions do not apply to SMSAs of less than a quarter of a million inhabitants. We suspect that urban areas which are small enough to have economies dominated by a single firm or a single industry *may*, as a consequence, have an occupational structure which is marked by the peculiarities of that firm's or that industry's hiring, firing and promotional practices. If these peculiarities include unusually high or low amounts of discrimination, or if they merely create unusual racial differences in occupational distribution without being atypically discriminatory, then places dominated by a single industry or firm will also tend to manifest atypical race-occupation relationships. (Spilerman and Habib, 1976, have considered similar peculiarities in the process of socioeconomic achievement in one-industry towns in Israel.) In contrast, large metropolitan areas tend to have large numbers of employers and diverse industrial compositions, making it difficult for the distinctive practices of a single industry or firm to dominate their occupational structure.

However, we found no large differences between our estimates of Spilerman and Miller's model (based on cities of 250,000 or more) and Spilerman and Miller's estimate of the model based on cities of 100,000 or more inhabitants. This lack of differences suggests that our results would not have differed substantially if we had included cities of 100,000 to 250,000 inhabitants in our analysis. Thus, we can find no reason to believe that our findings do not apply to both medium- and large-sized SMSAs.

We stress that we have *not* found that average levels of *prejudice* are the same in every SMSA. Much of the race relations literature that motivated this paper is based on the hypothesis that the proportion of a city's population that is black and the rate of change in that proportion affect the level of Negrophobia among the city's white residents, and that this Negrophobia, in turn, affects the severity of occupational discrimination against blacks. We have not examined evidence which is relevant to the link between black demographic characteristics and Negrophobia, and so we have no reason to comment upon this relationship. But if cities do not vary in the extent to which their black and white occupational distributions are differentiated, then there can be little reason to believe that demographic or industrial differences between cities are responsible for large differences in the race-occupation relationship. Thus, it would appear that if there are large city differences in Negrophobia, these differences do not cause substantial intercity variation in occupational differentiation between the races. The reason for this, we speculate, is that notions about the propriety of black employment in various occupations are probably more deeply connected with values and norms concerning occupations than with feelings of Negrophobia. Some amplification of this speculation seems in order, and we give some brief attention to it now.

Our reasoning about the causes of geographic "nondifferences" in occupational differentiation between the sexes and races is based on the emergent body of research and theory on the social evaluation of occupations and their incumbents.

For present purposes, only three arguments in this literature are important.

First, in modern Western societies, virtually all individuals seem to be able to make judgments about the social ranking of occupations (see Siegel, 1971).

Second, these social evaluations do not vary significantly across geographic areas (Hodge et al., 1966), between social groups (Reiss et al., 1961: ch. viii) or over relatively long time periods (see Hodge et al., 1964; Deeg and Patterson, 1947; Neitz, 1935). Indeed, Siegel (1970) has provided empirical evidence that U.S. blacks accord occupations the same prestige as given by whites (he finds a zero-order correlation of $+ .9625$ between the prestige rankings given to 66 occupations by whites and the prestige rankings given to these same occupations by blacks). Further, Siegel (1970: Figures 3 and 4) also finds that blacks are virtually identical to whites in the extent to which they downgrade the prestige of an occupation on the basis of the percentage of blacks in its labor force.

Third, the social evaluation of occupations includes judgments of the extent to which incumbency in each occupation is appropriate or inappropriate for members of various identifiable social groups, and these judgments create sex and race differences in occupational distributions. For example, the force of social custom in creating sex and racial differences in occupational distribution has long been recognized even by those whose major efforts have been focused on understanding the workings of the sexless, colorless and unprejudiced invisible hand that governs economic markets (e.g., Taussig, 1928; Arrow, 1971; 1972; Becker, 1957). Indeed, Rossi (1965:1198) has argued that women themselves tend to perceive an incompatibility between employment in scientific or professional occupations and the demands of marriage and childbearing, leading great numbers of females away from these occupations and into vocations which are more easily combined with a role-set centered on home and children. Thus, it would seem that the relative absence of women in certain occupations (and their relative preponderance in others) is probably due to *both* the un-

willingness of employers to hire females for certain jobs *and* the existence of matching widespread preconceived notions by women themselves that females are not suited to employment in certain fields (for some related ideas and evidence, see also Oppenheimer, 1970; Duncan and Evers, 1975).

Fitting the above three propositions together, one would conclude that judgments of sexual and racial appropriateness for incumbency in various occupations are extremely widespread, that they create racial and sexual differentials in occupational distribution, and that these judgments are sufficiently homogeneous that the race-occupation and sex-occupation relationships do not vary much from city to city. Thus, one might speculate that research on occupational evaluations implies that intercity variation in racial differences in occupational attainment should be small or nonexistent. That is, of course, precisely what we find. And while our research is hardly a test of this implication, our findings are entirely consistent with it.

A SOCIAL INDICATOR MODEL OF CHANGES IN THE OCCUPATIONAL STRUCTURE OF THE UNITED STATES: 1947-1974*

FRED C. PAMPEL

University of Iowa

KENNETH C. LAND

MARCUS FELSON

University of Illinois, Urbana

American Sociological Review 1977, Vol. 42 (December):951-964

This paper presents a ten-equation dynamic structural equation model that shows how aggregate changes in the occupational structure of the United States affect each other and are affected by economic, technological and institutional changes. The model postulates a recursive flow of causation from changes in sectorial (agricultural, manufacturing, services) demand and productivity to changes in the distribution of occupations by sector, bureaucratization and status level. Model equations are estimated on annual national data from 1947 to 1972 and are used to make conditional forecasts of the endogenous variables for 1973 and 1974. The equations fit the observed data well, lack demonstrable autocorrelation of disturbances, and forecast the 1973 and 1974 values with considerable accuracy. Empirically, the model facilitates the quantitative estimation of the relative effects of economic growth and technological change on expansion of the service economy, bureaucratization of jobs, and growth of high-status occupations. In particular, when combined with recent findings on the sources of intergenerational occupational mobility in twentieth-century American society by Hauser et al. (1975), the model shows how changes in the pattern of economic growth and productivity from that which has prevailed for most of the post-World War II period may imply a decline in the rates of upward occupational mobility in the absence of other counterbalancing structural changes.

As part of the general increase of interest in the development on noneconomic social indicators in recent years, there has been a corresponding rise in the number of aggregate indicators of social conditions of work in America that are available in time series form. For example, *Social Indicators: 1973* contained about a dozen annual and biennial times series of indicators of employment opportunities, labor force participation, working conditions, and quality of employment life, whereas *Social Indicators: 1976* contains roughly twice that number (Executive Office of the President, 1974; 1977). However, as has been true of most social indicator research in general, research on indicators of work and employment has concen-

trated on the accumulation and description of the indicators rather than on their analysis as components in social system models (Anderson, 1973; Land and Spilerman, 1975). In particular, in spite of the increasing availability of time series on changes in American working conditions, there exist no macro sociological models capable of explaining the causes and consequences of these social changes.

The objective of this paper is to begin to fill in this gap in the sociological literature. More precisely, we specify and estimate a ten-equation dynamic macro social indicator model that shows how aggregate changes in the occupational structure of post-World War II American society affect each other and are affected by changes in economic, technological and institutional forces. The model is dynamic, because it utilizes difference equations to explain rates of change in social indicators; it is macro, because it represents the structure of over-time interrelationships among indicators measured in the form of summary counts, averages, or rates defined on the population.

* This paper was presented at the annual meeting of the American Sociological Association, September 5-9, 1977, Chicago, Illinois. The research reported here was supported by Grant Number SOC75-09096 from the National Science Foundation. We are grateful to Joan Huber and Ross M. Stolzenberg for comments on an earlier draft of the paper. Any errors, obscurities or inadequacies that remain are, of course, the responsibility of the authors.

The model is based upon a theory of how economic, technological and institutional forces determine changes in the positional distribution of occupations among categories of sector location, bureaucratization and status. Theoretical and methodological strategies for specifying the model are sketched in the next section and individual equations for indicators of changes in the occupational structure are specified in detail and estimated in subsequent sections. Since the theory specifies no significant simultaneous interdependencies among the endogenous variables, the model is recursive at time t . Estimates of the model are obtained using annual national data from 1947 to 1972 and conditional forecasts of the endogenous variables of the model are performed for 1973 and 1974. Finally, implications of the empirical performance of the model for related issues in the study of social change and social mobility are discussed.

Model Specification: Strategies and Overview

This paper applies a general framework for building dynamic macro social indicator models laid out elsewhere (Land and Felson, 1976). That framework consists of three components: (1) a demographic accounting matrix equation for relating population stocks and flows between the component social states of a social condition in successive time periods by using transition coefficients, (2) an interpretation of the demographic accounting parameters (transition coefficients or their stock counterparts) as measures of opportunities of individuals or groups to realize social benefits by changing from one social state to another and (3) an explanation of changes over time in the opportunity structure as functions of aggregate social forces as modeled in a system of difference equations. Thus, a general function for determining changes in social indicators combines autoregressive terms (representing the "dynamic" response over subsequent time periods of the social condition to changes in its environment) and structural equation terms (representing causal hypotheses about relevant environmental changes that affect the so-

cial condition). Since the details of this approach are discussed elsewhere (Land and Felson, 1976), we do not repeat them here.

To proceed with the macro parameterization of changes in work and employment conditions, it is necessary to have at least the rudiments of a theory of macro social change. Given an opportunity-structures interpretation of stock and flow social indicators, it follows that this theory should be capable of accounting for changes in the structure of opportunities. Without pretending to offer a complete theory of change, Land and Felson (1976) suggest, as a theoretical guideline for the specification of dynamic social indicator models, that changes in stocks and flows of social indicators can be accounted for in terms of those social forces that affect the set of competing alternative opportunities. This general guideline assists the formulation of substantive hypotheses incorporating standard sociological, demographic and economic notions of norms, roles, stratification, conflict, population at risk, cohort replacement, demand, supply, cost, and so forth, insofar as they explain variations in the structure of opportunities for transition. As such, the guideline is useful if it facilitates the specification of equations that perform well empirically. It also allows reformulation of other theories and findings so as to be useful for model-building. The application of this theoretical guideline is best demonstrated in specific substantive contexts.

Figure 1 gives a general flow-graph description of how we apply the Land-Felson Opportunity Structures Postulate to the explanation of changes in indicators of occupational structure. To begin, we use the term "occupational structure" to refer to the distribution of jobs by various characteristics of economic performance roles. Although many such characteristics could be distinguished, we deal herein with three classes of job attributes that are relevant to sociological theory, can be measured at the aggregate level in time series form for the United States, and show substantial variation when so measured. The three are: (1) sectorial relocation, pertaining to the transfer of jobs from one economic sector to another; (2) bu-

Figure 1. Flow Graph for the General Structural Relations of a Model of Changes in the American Occupational Structure

reaucratization, pertaining to the organizational context within which jobs are located; (3) job upgrading, pertaining to the shift of jobs into higher status categories. In brief, the first category relates to the sectorial distribution of employment, the second to the organizational context of work and the third to the nature of the work done. Although Moore (1966) originally introduced similar characteristics of occupational structures in the context of economic development, Land and Pampel (1977) recently demonstrated their relevance for the description of contemporary social change.¹

The theory underlying the relationships graphed in Figure 1 can be characterized as postulating: (1) that changes in the sectorial distribution of jobs in the United States respond to changes in sectorial (economic) demand and (technological) productive efficiency; (2) that shifts in the sectorial location of jobs affect the distribution of jobs by degree of bureaucratization of the organizational context of work; and (3) that changes in the distribution of jobs by status level are determined by the sectorial relocation and bureaucratization of work. In other words, we argue that the means and extent of economic production in the society create and change the distributions of jobs among competing categories of sector, type of organization and status. Although the assumptions of

the model can be stated in this very general and simplified form, detailed arguments for the specification of individual equations are more complicated and are given in the following three sections of the paper.

Changes in the Sectorial Allocation of Jobs

Although more detailed schemes exist, we will utilize Clark's (1957) distinction between the primary (agricultural), secondary (manufacturing) and tertiary (services) industrial sectors of the economy because these categories maintain a degree of homogeneity of the type of work done in each sector that can be surpassed only by a considerably more detailed classification. Not only would a more detailed set of industrial categories require a greater number of structural equations for determining shifts of jobs among the sectors, but Clark's three-category scheme also has the advantage of having been used in other studies of contemporary social change. For example, noting that since World War II the United States has experienced substantial employment shifts into the service industries (which now constitute roughly 65% of employed persons), Bell (1973) characterized postindustrial society partly in terms of an increased economic orientation towards performance of services rather than production of goods.

Thus, in the model to be specified

¹ Some of the equations to be discussed expand and refine the analyses of Land and Pampel (1977).

Table 1. Ordinary Least-Squares Estimates of Sectorial Relocation Equations

(1.1) Percent Agricultural Employment	
$\%AGR_t = -3.4624 + 0.9988\%AGR_{t-1} + 0.1667AGRGNP_t - 164.5000AGRPROD_t$	
$(1.4377) \quad (13.1080) \quad (1.7158) \quad (1.1800)$

$\bar{R}^2 = .9930 \quad SEE = 0.2397 \quad DW = 1.6975 \quad df = 20$	
(1.2) Percent Service Employment	
$\%SER_t = 26.0350 + 0.6191\%SER_{t-1} + 0.0330SERGNP_t - 1781.5000SERPROD_t$	
$(2.9800) \quad (3.4335) \quad (3.1241) \quad (2.3454)$	
+e _t	
$\bar{R}^2 = .9554 \quad SEE = 0.7996 \quad DW = 1.6855 \quad df = 20$	
(1.3) Percent Manufacturing Employment	
$\%MAN_t \equiv 100 - \%AGR_t - \%SER_t$	

Variables: %AGR = percent of civilian labor force in agriculture, forestry, hunting and fishing industries; AGRGNP = gross national product of agriculture industries in billions of 1958 dollars; AGRPROD = agricultural productivity defined as agricultural gross national product per 1,000 agricultural employees; %SER = percent of the civilian employed labor force in service industries, i.e., transportation, communication, utilities, wholesale, retail, finance, insurance, real estate, services, and government; SERGNP = gross national product of service industries in billions of 1958 dollars; SERPROD = service productivity defined as service gross national product per 1,000 service employees; %MAN = percent of the civilian employed labor force in construction and manufacturing industries.

herein, we begin with equations determining the percentages of the civilian labor force employed in the agriculture, manufacturing and services industries.² Two classes of economic and technological factors are postulated to account for annual shifts in sectorial employment (Clark, 1957; Moore, 1966): (1) changes in demand for different types of goods and services and (2) changes in the state of production technology as it affects the proportions of capital and labor necessary at each stage of the production process.³ Specifically,

our equations for shifts in sectorial employment rest upon the following two propositions. First, other things equal, an increase in the demand for a sector's product increases employment opportunities in that sector. Second, other things equal, increases in labor productivity in a sector—primarily due to the replacement of human labor by machine labor—reduce the opportunities for employment in that sector. For the purposes of the present model, we take changes in economic demand and production technology as exogenous.⁴

On the basis of these two propositions, we specify that demand will be related positively, and labor productivity negatively, to percent sector employment. Indexing demand by sector gross domestic product and productivity by sector product per worker gives the first two equations of Table 1. The third equation in Table 1 obtains percent manufacturing

² Some extant macro econometric models (e.g., the Wharton model as described in McCarthy, 1972) contain stochastic equations determining the numbers of workers in various industrial sectors, from which the percent sector employment can be obtained by an algebraic identity using the total number of civilian employees as a base. Because of the intrinsic interest of the relative sizes of industrial employment in sociological theories, however, we estimate percent sector employment by direct stochastic formulation of the forces that account for sectorial relocation of jobs.

³ In the context of economic development, Moore (1966) cites a third class of factors responsible for employment shifts, namely, changes in institutional requirements and constraints. For post-World War II American economy, however, changes in both macro and micro social and economic policies are likely to be revealed either in changes of sectorial demand or productivity. Thus, we expect little loss of explanatory power by focusing on the latter two

factors within the context of this historical period for American society.

⁴ Yearly changes in sector demand are usually determined by the Keynesian components of annual macroeconometric models, whereas the rate of change in the substitution of machine labor for human labor typically are handled in the neoclassical production function components of such models; see, for example, Hickman and Coen (1976).

employment (%MAN) by an algebraic identity, which closes the system of the three equations by forcing the predicted, as well as the observed, values to sum to 100 percent.

The equations in Table 1 present metric regression coefficients estimated by ordinary least-squares; t-ratios calculated from the coefficients divided by their standard error in parentheses beneath the coefficients; the squared multiple correlation coefficient adjusted for degrees of freedom (\bar{R}^2); the standard error of estimate (SEE); the Durbin-Watson autocorrelation statistic (DW); and the degrees of freedom (df) in the estimated equations. The equations are estimated for the years 1957 to 1972. However, the number of observations will vary from equation to equation depending on the availability of appropriate data for all the years (see Appendix for data sources).

In addition to the exogenous variables, the two stochastic equations of Table 1 include a lagged endogenous variable. When the values of an endogenous variable take more than one time period (a year in the present model) to adjust to changes in the exogenous or other predetermined variables of the equation, it is necessary to introduce an expression for the rate of change in the endogenous variable with respect to time (Blalock, 1969; Coleman, 1968). Since we are dealing with data in the form of discrete time series, we introduce a finite first-difference $\Delta y = y_t - y_{t-1}$ to account for the behavior of such variables.⁵ When estimated in autoregres-

sive form (i.e., with a lagged dependent variable), such equations allow the rate of adjustment in the endogenous variables per year to be estimated by subtracting the estimated coefficient of the lagged endogenous variable from one (Goldberg, 1958).

Applying this interpretation to equation (1.1) of Table 1, we see that the rate of adjustment of percent agriculture (%AGR) to changes either in demand for agricultural products or in agriculture productivity is very slow: a change of one unit in either of these exogenous variables leads to an adjustment of only 0.0012 units per year in %AGR towards its equilibrium value. This exceedingly slow rate of adjustment of agricultural employment to changes either in demand or in productivity corroborates similar findings for the rate of adjustment of the percent of the population living on farms to changes in the ratio of farm to nonfarm income (Land and Felson, 1977). It also accounts for the highly significant t-ratio of the lagged term in equation (1.1).

Other aspects of the %AGR equation indicate reasonably good performance. With its very slow adjustment rate, the \bar{R}^2 is expectedly high and the standard error is correspondingly small. The latter statistic indicates that, under the assumption of independently and normally distributed disturbances, the observed %AGR should be within 0.48% of the predicted value 95% of the time. The one-tailed probability of the AGRGNP is .05, while that of AGRPROD is only .11. Finally, the Durbin-Watson statistic is large enough to fail to reject the null hypothesis of zero autocorrelation among the disturbances of the equation at the .05 level.⁶ In brief, the

⁵ In the case of the simplest possible linear functional form, we let the amount of change in y -values from time $t-1$ to time t be a function of the value of y at time $t-1$ and the values of the exogenous values which we denote for convenience by the constant a :

$$\Delta y = y_t - y_{t-1} = a + b y_{t-1}.$$

By adding y_{t-1} to each side of the equation, we obtain

$$y_t = a + b^* y_{t-1}$$

where $b^* = b+1$. This is in a form convenient for statistical estimation (cf. Land and Felson, 1976:579-97). Substantively, if the value of the endogenous variable does not adjust within one time period to changes in the exogenous variables, this will show up statistically in the form of a significant regression coefficient for the lagged dependent variables. Conversely, if the value of the endogenous variable is at or very near its implied equilibrium

value within one time period after a change in the exogenous variables, then the lagged dependent variable will have an insignificant estimated regression coefficient. For a more detailed discussion of the behavior of sequences of y -values and the implied equilibria under different values of a , b^* and y_0 , see Goldberg (1958:86) and Land and Felson (1976).

⁶ The Durbin-Watson test statistic was constructed for testing for autocorrelation of disturbances in regression equations that do not have lagged dependent variables present on the right-hand side, and it is well known that the statistic is biased toward acceptance of the null hypothesis of zero

empirical estimates of the %AGR equation conform relatively well to our theoretical arguments.

The statistical properties of equation (1.2) of Table 1 for determining the percent service (%SER) can be similarly interpreted. The estimated rate of adjustment of %SER to changes in demand and productivity, approximately 0.38% per year, is much faster than that for %AGR. Both the demand and productivity indices have significant estimated coefficients in theoretically expected directions. From the larger direct effect of the demand index (SERGNP) relative to the productivity index (SERPROD), it can be inferred that the increase in %SER is due more to increased demand than to increased productivity, a finding consistent with that of Fuchs (1968).

In terms of implications for overall trends in sectorial relocation of jobs, the negative estimated value of the constant term in equation (1.1) indicates that %AGR is declining, whereas the positive estimated value of the constant term in equation (1.2) indicates that %SER is increasing. Depending on what is happening to the percent of the labor force employed in manufacturing, the increase in %SER could be at the expense either of %AGR or of %MAN. Actually, %MAN oscillates around a relatively constant level because increased demand has been balanced by increased productivity (Land and Pampel, 1977). For instance, %MAN was 33.6 in 1950 and 32.2 in 1970. Thus, we infer that the relative growth of the service sector has been primarily at the expense of the agricultural sector, a finding consistent with Nordhaus (1972).

autocorrelation of the disturbances when a lagged variable is present. However, simulation studies for models similar to those used herein have shown that use of a number at or near the "upper bound" of the statistic for determining critical region of the test statistic will correct for the bias in most cases (Taylor and Wilson, 1964). For this reason, and because it is customary to report the Durbin-Watson statistic in statistical analyses of econometric models that contain lagged dependent variables, we follow that practice here, recognizing that there is no basis in statistical theory for a strict probability interpretation of the statistic.

Changes in the Bureaucratic Organization of Jobs

We now turn to the implications of these sectorial relocation trends for changes in the organizational context of work. In particular, we examine the consequences of the post-World War II sectorial relocation of American jobs from agriculture to service industries for the extent to which jobs are concentrated in large formal organizations.

Measurement of structural attributes of bureaucratization of organizations at the societal level is typically based on concepts: (1) structured communication, (2) specialization and division of labor, (3) hierarchical authority and (4) the need for expert, specialized training. For example, Frisbie (1975) developed indices of these concepts suitable for use in cross-cultural analysis. Our measures are based on the same concepts, but the use of annual, national data requires that our operationalizations differ slightly from those of Frisbie. First, following Stinchcombe (1965) and Frisbie (1975), level of structured communication is indexed by the percent of the labor force employed in clerical positions. Structured, written communication requires clerical workers to process official documents. Second, the Gibbs-Martin index is used to measure division of labor. This measure reflects the differentiation of jobs among nine industries (Gibbs and Martin, 1962; Labovitz and Gibbs, 1964).⁷ Third, Frisbie (1975) used proportion of the labor force in administrative, executive and managerial occupations to operationalize hierarchical structure. However, annual data for the United States groups both self-employed and wage and salary administrators, executives and managers together. Inclusion of

⁷ The calculating formula for the Gibbs-Martin index is

$$\text{DIVLAB} = 1 - (\sum X_i^2 / (\sum X_i)^2)$$

where X_i is the number of persons in each industry (Gibbs and Martin, 1962). The index is at its maximum when workers are evenly dispersed throughout the industries. The industries used to calculate the index are agriculture, construction, manufacturing, transportation and utilities, wholesale, retail, commerce, service, and government.

self-employed makes the measure unsuitable. The surrogate index used, recommended by Bendix (1956:211) as the single most useful measure of the internal bureaucratization of the occupation structure, is the percent wage and salary employees. While not a direct measure of hierarchical authority, percent wage and salary workers does reflect the transfer from self-employment to work in larger, bureaucratic organizations. Fourth, we will not concern ourselves with the fourth characteristic, expert training, since changes in educational variables have been studied elsewhere (Felson and Land, 1977). Finally, since these measures of bureaucratization may correlate with other changes in industrialized societies, we concentrate on changes in the indicators themselves rather than attempting to measure some underlying dimension of bureaucratization.

Our objective here is to account for the trends and fluctuations in these aggregate bureaucracy indices. To do so, we utilize two distributional relationships. First, for a variety of reasons having to do with the technology and scale of production, the average number of employees per economic unit in agriculture tends to be smaller than the corresponding average in

the manufacturing or services sectors, and the proportion of units that is very small (one to three employees) tends to be larger in agriculture than in manufacturing or services (Land and Pampel, 1977). Furthermore, not only do service organizations tend to be larger, on the average, than agricultural establishments, but there was a greater increase in the average size of service establishments than in the average size of agricultural (or manufacturing) establishments during the period 1948-1973 (Land and Pampel, 1977). On the basis of these structural relationships, it can be inferred that a shift of workers out of agriculture into services tends, on the average, to put them into larger organizations. Since larger organizations tend to be more bureaucratic than smaller ones, it follows that the sectorial relocation of workers from agriculture to services should produce increases in our indices of the bureaucratic organization of jobs.

From this discussion, we are led to specifications of annual changes in our indices of bureaucratization as increasing functions of percent manufacturing and, especially, percent service employees. This structure is exhibited in the estimated equations of Table 2. In addition, equation

Variables: %WAGSAL = the number of wage and salary workers as a percent of the civilian employed labor force; UNR = the unemployment rate defined as the yearly average of the number of employed persons 16 years and over as a percent of the civilian labor force; %CLER = the number of clerical and kindred workers as a percent of the civilian employed labor force; DIVLAB = Gibbs-Martin index of inter-industry division of labor, using a nine-industry classification of employed wage and salary workers.

(2.1), which determines the percent of the civilian labor force employed as wage and salary workers (%WAGSAL), contains the aggregate unemployment rate as an index of cyclical changes in the demand for workers.

The estimated coefficients of equation (2.1) reveal several interesting properties. First, they show that the direct impact on %WAGSAL of a one percentage point increase in %MAN is less than two-thirds the size of the direct effect of a one percentage point increase in %SER. This is consistent with the findings on sectorial relocation during the estimation period that were noted in the preceding subsection. Second, the small negative, but insignificant, estimated constant term shows that the population constant term is near zero or even negative. Combined with the dynamics of the difference equation, this implies that the implied equilibrium values for %WAGSAL would be very small if %MAN and %SER took on increasingly small values. Thus, the dynamics of the equation are consistent with the relative scarcity of wage and salary work in a predominantly agricultural society. The other coefficients of the equation show that the effect of business cycles on wage and salary employment is substantial and that the adjustment rate of %WAGSAL to changes in the predetermined variables is about 0.53 percentage points per year. Finally, the summary statistics for the equation show that it tracks the time path of the dependent variable very well and that the null hypothesis of zero autocorrelation of the disturbances cannot be rejected.

Consider next the numerical properties of equation (2.2) which determines our index of the extent of structured communication in organizations, namely, the percent of employees in clerical and related occupations (%CLER). In this case, the sizes of the estimated direct effects of %MAN and %SER are of more nearly equal magnitude, and the annual rate of adjustment of the equation towards equilibrium is somewhat slower than that of the preceding equation. However, the significant negative constant term corroborates the observation made above about the smaller degree of implied bureau-

cratization for predominantly agricultural societies. Again, the summary statistics show that the equation performs well.

The final equation of Table 2 represents our attempt to index changes in the third indicator—specialization and division of labor. For this purpose, we study annual changes in the Gibbs-Martin (GM) index of the division of labor among nine industrial categories for employed wage and salary workers. Not only does the GM index have some defects as a measure of the classical notion of the division of labor (Gibbs and Martin, 1962), but it would be preferable to apply the index to a classification of workers by detailed job categories rather than by industries (Labovitz and Gibbs, 1964). Nevertheless, even with these limitations of the index and the data, the estimated coefficients of equation (2.3) yield to an interpretation of the sectorial relocation of workers into services as leading to a greater dispersion of jobs among the industries and, hence, to a greater division of labor index. On the other hand, an increase in %MAN leads to greater concentration among the manufacturing industrial categories and consequently decreases the value of the GM index. With a constant term of about 0.56 and an adjustment rate of about 0.70 units of the GM index per year, the implied equilibrium value of the index at zero levels of %MAN and %SER is about 0.81. This is not inconsistent with other empirical results on the division of labor in more rural societies. For example, using the 253 detailed occupations in the United States Census of 1900 to classify workers, Labovitz and Gibbs (1964) obtained a value of 92.2 for the GM index. In brief, the numerical properties of equation (2.3) are meaningful. However, its overall statistical performance is not as good as that of the other two equations in Table 2; in particular, its Durbin-Watson statistic is indeterminate with respect to the null hypothesis of no autocorrelation of the disturbances. Thus, the equation may be somewhat misspecified, and we reserve judgment until we examine its forecasting performance.

In summary, we find that post-World War II trends and fluctuations in the sectorial relocation of jobs account reason-

ably well for changes in aggregate indices of the extent to which jobs are bureaucratized in American society. We have argued that this effect is transmitted through an increase in the mean size of the organizations into which the jobs are moved relative to those from which the jobs came. Although the data on changes in the mean size of organizations are not sufficiently detailed and frequent to be used in our time-series model, the extant fragments of data do not contradict this explanation.

Changes in the Status Distribution of Jobs

In addition to their consequences for the bureaucratization of work, our model postulates that changes in the sectorial location of jobs account for the post-World War II movement of jobs up the status scale (Land and Pampel, 1977), a movement usually referred to as "upgrading" (Moore, 1966). The basic distributional mechanisms through which this effect occurs in our model are as follows. First, shifts of jobs out of agriculture tend to decrease opportunities for employment in farming and farm-related occupations, which are among the lowest status categories (Blau and Duncan, 1967:277-94). Conversely, the shift of jobs into the manufacturing and service sectors creates greater opportunities for employment at the upper end of the status scale, since jobs in the non-agricultural sectors tend to have greater concentrations in the higher status categories than do those in agriculture (Blau and Duncan, 1967:23-162). The combined effects of these movements at the tails of the status distribution of occupations lead to an increase in its moment of gravity (central tendency, mean). Moreover, increases in jobs at either end of the status scale should be positively associated with the dispersion of the occupational distribution among status categories. However, the total numerical empirical effect of changes in densities at the tails on dispersion of the status distribution will depend not only on the relative sizes of the changes but also on their respective weights in determining the dispersion. Second, large bureaucracies

(created by sectorial relocation out of agriculture) tend to employ more highly trained technicians, professionals and managers than do small organizations, since increasing bureaucratization, on the average, means more specialization and division of labor, as we noted above. Therefore, we expect an aggregate increase in bureaucratization to be associated with job upgrading. These mechanisms lead directly to the specifications of the equations reported in Table 3.

Examining these equations, we find that the estimated coefficients of equation (3.1) in Table 3 for determining changes in the percent of the employed labor force in professional and related occupations (%PROF) show that an increase of one percentage point in either %MAN or %SER translates into a direct impact of about 0.27%. This implies that the proportions of new jobs in either sector that fall into the PROF category are approximately equal. The sizes and statistical significance of the constant and lag terms are consistent with the interpretations that we have given to the equations in Table 2. Furthermore, the summary statistics for the equation indicate good overall statistical performance with no autocorrelation of the disturbances.

The estimated constant term and lag coefficient of equation (3.2) for the percentage of the labor force employed as farm managers or farm laborers (%FARM) can be given an interpretation similar to that for %PROF, except that the coefficient of annual adjustment toward equilibrium is larger for %FARM than for %PROF. In addition, the estimated coefficient of %AGR in this equation shows that a one percentage point decline in %AGR translates into a direct decline of about 0.95% in %FARM. In other words, roughly 95 percent of the decline would be in farm managers and farm laborers. In terms of summary statistics, the equation accounts for most of the variation in the %FARM time series and has a small standard error of estimate, but its Durbin-Watson statistic is in the "indeterminate" region, so that some autocorrelation of the disturbances may be present.

The last two equations of Table 3 determine changes in the mean (MOS) and

Variables: %PROF = the number of professional, technical, and kindred workers as a percent of the civilian employed labor force; %FARM = number of farm managers and farm laborers as a percent of the civilian employed labor force; MOS = mean occupational status of civilian employees in Census SIO units weighted by the distribution among occupational categories of civilian employees; SDOS = standard deviation of occupational status in Census SIO units.

standard deviation (SDOS), respectively, of the distribution of occupations by status.⁸ Both equations have good overall statistical properties and are consistent with the arguments stated above, but the

⁸ The mean and standard deviation indices of the status distribution of occupations are calculated by weighting the annual distributions among eleven occupational categories of civilian employees by the U.S. Census Bureau's Status Index of Occupations (SIO). The SIO is based upon the combination of average levels of education and income for employed males by occupation in 1950. For details on the construction of the index, see U.S. Bureau of the Census (1967). Of course, by using a single status index to scale annual reports of the distribution of American occupations, we are implicitly assuming that the statuses of occupations are temporally stable enough during the post-World War II period to make a comparison of annual values of MOS and SDOS meaningful. On this point, see Blau and Duncan (1967:120-1). In addition, there exist several alternative status scales besides the Census SIO scale that could be used to calculate MOS and SDOS. Nevertheless, since these scales are highly intercorrelated with each other, our findings should be quite robust to the particular scale used. Finally, it goes without saying that, provided the data were available, it would be preferable to calculate our MOS and SDOS indices on detailed annual job distributions rather than on the eleven summary categories that we have used. However, the basic qualitative properties of our model should be invariant to calculations based on more refined classifications.

difference between the two are noteworthy.

First, whereas the adjustment of MOS to changes in the predetermined %CLER, %PROF, and %FARM is immediate (the lagged dependent variable is not statistically significant and, thus, is dropped from the equation), the annual rate of adjustment of SDOS is relatively slow (0.27). From this, we infer that the predetermined variables in the MOS equation are sufficient to account for the year-to-year changes in the index, but that the time path of SDOS apparently reacts to changes in other occupational categories besides PROF and FARM. In fact, it may be the case that changes in the latter set off a chain reaction of changes in other categories that culminates in a slow reaction rate for SDOS.

Second, whereas the negative coefficient of %FARM in the MOS equation is only a fraction of the coefficients of %PROF and %CLER, the positive coefficient of %FARM in the SDOS equation is slightly larger than that of %PROF. On this basis, we infer that the movement of jobs into the PROF and CLER categories has been more important in raising MOS than has been the movement out of farm-

Table 4. Conditional (*Ex Post*) Forecasts of the 1973 and 1974 Observed Values of the Stochastically-Determined Social Indicators

	1973				1974			
	Observed	Forecast	Forecast Error ^a	Percent Error ^b	Observed	Forecast	Forecast Error ^a	Percent Error ^b
%AGR	4.1	4.2	-0.1	2.4	4.0	3.6	0.4	10.0
%SER	64.2	66.2	-2.0	3.1	66.5	66.8	-0.3	0.5
%WAGSAL	90.3	90.3	0.0	0.0	90.4	90.5	-0.1	0.1
%CLER	17.2	17.5	-0.3	1.7	17.5	17.5	0.0	0.0
DIVLAB	.8324	.8374	-.005	0.6	.8332	.8418	-.0086	1.0
%PROF	14.0	14.3	-0.3	2.1	14.4	14.5	-0.1	0.7
%FARM	3.6	3.5	0.1	2.8	3.5	3.5	0.0	0.0
MOS	59.7	59.7	0.0	0.0	60.2	60.1	0.1	0.2
SDOS	22.17	22.25	-0.08	0.36	22.11	22.20	-0.09	0.41

^a Error = Observed Value — Forecasted Value.

^b Percent Error = (Observed Value — Forecasted Value/Observed Value) × 100.

ing occupations. But the direct effect of a one percentage point decline in %FARM on decreasing the dispersion of occupations by status is slightly larger than the direct effect of a comparable percentage increase in %PROF on increasing the dispersion.

Empirically, from 1947 to 1972, the %PROF category increased 7.4 percentage points from 6.6% to 14.0%, the %CLER category increased 5.0 percentage points from 12.4% to 17.4%, and the %FARM category declined 6.5 percentage points from 8.5% to 2.1%. Combined with equations (5.3) and (5.4), we find that the changes in %PROF and %CLER account for most of the increase in the center of gravity of the status distribution of occupations, whereas the dispersion of the distribution has an overall decline due to a greater direct impact (decline times the estimated parameter) of %FARM on SDOS than of %PROF.

Forecasting with the Model

While social forecasting usually is not an integral part of sociological analyses based upon cross-sectional survey research, the prediction of postestimation sample period values of the endogenous variables conditional on observed values of the predetermined variables (usually referred to as *ex post* forecasting) is a natural outgrowth of the time-series estimation of a dynamic macro social indicator model (Land and Felson, 1976:596-8). Not only are substantive forecasts feasible

in the context of a dynamic model, but they also provide a statistical means for further evaluating the model's adequacy. If the equations we have constructed actually reflect causal mechanisms and are not simply exercises in curve fitting, then forecasts of subsequent timepoints of the dependent variables, conditional on observed values of the exogenous and predetermined variables, should be relatively accurate. That is, in the absence of true structural change (which can never be completely discounted), a conditional forecast is another means of determining the impact of many possible sources of error on the obtained parameter estimates.

Since the estimation sample period of our model is 1947 to 1972, we can make *ex post* single-year forecasts for subsequent years. Table 4 reports the observed values, forecast values, forecast errors, and percent errors (as a percentage of the observed values) for the endogenous social indicators of our model for which data for 1973 and 1974 are available. As can be seen, the forecasts are accurate for the most part. Specifically, for 1973, none of the forecast errors is greater than 2.5 times the standard errors of the corresponding structural equations, and most of the forecasts are in error by a fraction of the standard errors.⁹ A similar remark

⁹ In making these comparisons, we have used the standard errors of the structural equations. This is a rather strong criterion, since standard errors of post-sample period forecasts will usually be larger

applies to the 1974 forecasts with the exception of the DIVLAB forecast which has an error about 4.5 times as large as the standard error of its equation. This is consistent with our previous analysis of the possible misspecification of this equation, and it suggests that the equation may need reformulation and/or reestimation.¹⁰ The forecast error of %AGR in 1974 is less than twice the standard error of the equation, but, because of the small observed value of %AGR, the percentage error is large. This underestimate of the 1974 value may result from a drop in 1974 farm prices and agricultural GNP. As discussed previously, the rate of adjustment in %AGR to exogenous changes is quite slow and the effects of the drop in 1974 prices may not be felt completely for a few years.

Overall, the forecasts in Table 4 are quite accurate, with 4 out of 18 forecasts having *no* errors. Since 1973 and 1974 were years of early economic expansion followed by a contraction due to the "energy crises" beginning in late 1973, and since these years have proven, therefore, to be particularly difficult for macro econometric models to forecast, such results for our model are promising.

Discussion of the Model

Now that the detailed equations of the model have been presented, several of its general features may be discussed. First, while we have taken changes in sectorial demand and production efficiency as exogenous to the present model, we do not assume that they are absolutely exogenous to the socioeconomic system. Each category of variables can be endogenized by the integration of the present model with models of changes in economic demand and production

technology. Second, although we have postulated a recursive causal structure for the variables of our model with no explicit feedback relationships from aggregate changes in the occupational structure to changes in aggregate sectorial demand or technology, we recognize that such feedbacks may exist through aggregate changes in life styles, through aggregate increases in managerial efficiency, and so forth. However, not only are these effects likely to be quite indirect, but they also are likely to involve substantial time lags. Consequently, there probably is little simultaneity bias in our estimates due to the recursivity assumptions.

The empirical properties of our model are relevant to those classical and contemporary theories of social change that have placed great emphasis on the role of technological and economic change in societal development. For example, two goals of Ogburn's work were to examine how society adjusts to the technological environment (Ogburn, 1950) and how the business cycle affects society (Ogburn and Thomas, 1922). Other classical theorists have examined the role of technology on broader societal development and social equality, while Bell (1973) has discussed the implications of technological change for the United States in recent decades. Although it is not our goal to evaluate these theories, become involved in the controversy over the primacy of technological or cultural factors in social change, or offer an alternative theory of social change, we have demonstrated in precise, quantitative terms the impact of economic and technological change on several aspects of post-World War II America.

Our results are also pertinent to questions raised by recent mobility research. Hauser et al. (1975) have separated the amount of mobility due to the association between father's and son's occupation from that due to the changing marginal distribution of occupations. They found that changes in the marginal distribution of the American occupational structure have been primarily responsible for increased rates of upward intergenerational mobility in the twentieth century and suggested that students of mobility pay

than their sample-period counterparts (for a derivation of and discussion, see, for example, Goldberger, 1964:169-70).

¹⁰ For instance, if no theoretically acceptable alternative specification can be found that performs better than equation (4.3), then it could be reestimated using a statistical technique that does not assume zero autocorrelation of disturbances such as the Cochrane-Orcutt iterative estimation process (Cochrane and Orcutt, 1949).

more attention to the causes of change in occupational distributions. Our model demonstrates the effect of several factors on the growth of high status occupations in the United States since 1947. Technological improvements in agriculture have allowed replacement of farm and farm-related human labor by machine labor, thereby reducing the number of farmers; the consequences of the resulting sectorial relocation and bureaucratization of work have been closely tied to the expansion of high status technical and professional occupations.

The societal implications of these structural relationships are clear. While changes in sectorial demand and productive efficiency were substantial during the 1947-1972 period, the rates of change in these driving variables of our model have decreased in the 1970s. If these rates of change continue to decline, then our model leads to the conjecture that there may be a contraction in the rate of growth of high status jobs. Combined with the Hauser et al. (1975) findings, this implies a decline in rates of upward occupational mobility in the absence of other counterbalancing structural changes.

As a concluding note, we emphasize that the model presented here is only a "baseline" model. Clearly, there are many aspects of aggregate changes in the sectorial location, bureaucratization and upgrading of work in contemporary American society that we have not been able to incorporate into our model. As new and improved social indicator time series become available, surely this initial model can be extended and/or replaced.

APPENDIX

Sources for Time Series Data

AGRGNP, SERGNP: Economic Report of the President, 1974, U.S. Department of Commerce.
%WAGSAL, %CLER, %PROF, %FARM, MOS, SDOS: Manpower Report of the President, various years, U.S. Department of Labor; MOS and SDOS were calculated from published figures; note also that inclusion of 14-15-year-olds in the collection of the data before 1958 may have a depressing effect on MOS, %PROF and %CLER since 14-15-year-olds generally hold low status jobs.

UNR: Handbook of Labor Statistics, 1975-Reference Edition, U.S. Department of Labor.
%AGR, %SER, AGRPROD, SERPROD: estimates of sector employment were obtained from Labor Statistics published by the Organization for Economic Cooperation and Development; the variables include all employed workers-agriculture, non-agricultural, self-employed, wage and salary, private and public; the details of estimation are presented in Land and Pampel (1977).
DIVLAB: Manpower Report of the President, 1975, U.S. Department of Labor; the index includes only persons employed on payrolls of non-agricultural establishments.

THE STRUCTURE OF INEQUALITY AND THE PROCESS OF ATTAINMENT*

AAGE B. SØRENSEN

University of Wisconsin, Madison

American Sociological Review 1977, Vol. 42 (December):965-978

This paper proposes a model for the process of attaining occupational status and income, where change in attainment is generated by the creation of vacant positions in social structure. The distribution of attainments, or the structure of inequality, is assumed fixed and is described by a simple exponential or geometric distribution function (depending on whether attainment levels are assumed discrete or continuous). Persons leaving the labor force create chains of vacancies in this structure that present mobility opportunities for persons entering the labor force. The implications of the model for the attainment process derived from these considerations for status attainment research and stochastic models for job mobility are discussed.

Introduction

Research on social mobility, status, and income attainment in sociology always has been heavily oriented toward the methodological problems posed by the subject matter under investigation. Thus, the development of indices in mobility research and problems of estimation and measurement in status attainment research have received a great deal of attention. Conceptual issues have been much less of a concern, although they have not been entirely unimportant. The concern for separating structural and exchange mobility in the development of indices of mobility and the concern for the temporal ordering of variables and for causal directions in status attainment research, reflect theoretical assumptions regarding the

forces that generate mobility and achievement. Nevertheless, the dominant research strategy has been inductive, rather than deductive: the accumulation of empirical findings from cross-national and cross-temporal studies is believed to produce a pattern from which a sociological theory of attainment and mobility will emerge.

This situation is in sharp contrast to the approach in economics to the study of one aspect of the attainment process—income attainment. Neoclassical economists have applied a powerful conceptual apparatus to income attainment in the form of human capital theory. The attainment of income in this perspective is conceived of as reflecting a person's productivity as determined by his/her ability and skills. Skills are obtained through education and training at a cost primarily in the form of earnings foregone. Returns on the investments in training and education are obtained in a competitive market where earnings are determined by the marginal productivity of labor. A number of empirical predictions can be derived from this theory—the shape of the age-earnings profile, the impact of wage differentials on demand for education, the allocation of training costs for general and specific on-the-job training, etc. A list of other derivatives from the theory is presented by Becker (1964:7-8). Few such predictions can be made from sociological research on at-

*An earlier version of this paper was presented at the Jerusalem Seminar on Mobility and Social Stratification under the auspices of the ISA committee on Social Stratification, Jerusalem, Israel, April 28-30, 1976. The research reported here was supported by funds granted to the Institute for Research on Poverty at the University of Wisconsin, Madison by the Department of Health, Education, and Welfare pursuant to the Economic Opportunity Act of 1964. The opinions expressed are those of the author. I am especially grateful for the very helpful suggestions in revising this paper provided by Nancy Tuma.

tainment processes where there is heavy emphasis on estimating the relationship among observed variables, not on modeling the process that produces the observed outcomes.

Human capital theory provides powerful predictions about the attainment process, but this does not mean that it is the only possible, or necessarily the most useful approach to the study of attainment processes. Some basic predictions from the theory do not square well with reality: from the theory one would predict that changes in the distribution of education would alter the distribution of incomes because of the changed supply at different skill levels. Since World War II, no such change can be observed in the distribution of income despite a marked shift in the distribution of education (Thurow and Lucas, 1972). Numerous criticisms of the theory also have been raised because of its apparent failure to account for the processes that are believed characteristic of important segments of the labor markets (Doeringer and Piore, 1971; Thurow, 1975).

Criticisms against a powerful theory, based on the failure of the theory to account for some empirical observations, are often ambiguous. Those who believe in the theory can usually come up with modifications that will save the theory by extending it and altering less important assumptions. Usually, human capital theorists are willing to allow for imperfections in the degree to which the real world approximates the neoclassical world that they assume. These imperfections then may be used to excuse the apparent failure of some empirical predictions. Further, they can point with considerable merit to the theory's ability to account for a number of basic features of observed processes and to the inability of critics to come up with an alternative theory equally parsimonious and with equal explanatory power. Theories are replaced with other theories, not with a set of isolated empirical observations that are subject to different interpretations.

The conception of mobility used in much traditional mobility research could be a point of departure for the formulation of an alternative theory of the attainment

process because of the contrast it provides with basic assumptions of human capital theory.¹ In human capital theory, changes in attainment are assumed to be brought about exclusively through changes in a person's productivity, i.e., skills and experience. The distribution of skills, in turn, is reflected in the distribution of earnings. In traditional mobility research, change in attainment, in contrast, is assumed to reflect changes in positions in a predetermined structure of inequality, without accompanying changes in personal characteristics. Persons can move only to a slot that is available, i.e., vacant, and while a person's "productivity" (as measured by ability, education, and experience) determines which slots a person gets access to, the distribution of attainments reflects the distribution of slots, not the distribution of personal attributes that are relevant for getting access to slots. Such a notion would be consistent with the lack of change in the income distribution in the face of a marked change in the educational distribution that is contrary to the implication of the neoclassical economic theory. It also would be consistent with the attainment processes that characterize primary labor markets (Doeringer and Piore, 1971) and job competition (Thurow, 1975) in the critiques of the neoclassical theory.

The sociological conception of mobility, however, has never been very well specified. It has been used to justify many attempts at separating structural from exchange mobility in intergenerational mobility tables, but this is a decomposition of the total amount of mobility in society, not

¹ The description of the neoclassical economic theory given here may be faulted for characterizing the theory as only a theory of supply, i.e., human capital theory. There is a demand side, that is marginal productivity theory. However, most theoretical and empirical work by economists on the earnings attainment process has focused on the supply side and, for this reason, the characterization seems justified. It could be argued that what follows in this paper is a specification of the impact of demand on the attainment process. The argument, however, would imply that the attainment process can be seen as a matter of supply and demand. This is not necessarily an appropriate conception. For a further discussion of these issues, see Sørensen and Kalleberg (1977).

a specification of the mechanisms of mobility generated by the creation of vacant positions in social structure. Further, since the objective here is to formulate a theory of the attainment process, the focus should be on intragenerational mobility rather than on intergenerational mobility as in most traditional mobility research.

Two tasks need to be carried out. It is necessary to specify how the creation of available or vacant positions generate mobility, and it is also necessary to specify how individual characteristics influence a person's utilization of mobility opportunities. Only a few attempts have been made at carrying out these tasks. With respect to the first task, works by Bartholomew (1972) and White (1971) are the main examples. White's (1971) vacancy-chain model is particularly suggestive of how structurally created opportunities generate mobility by generating chains of vacancies. However, the specification of how individual characteristics influence the utilization of vacancies is not attempted in White's work. Some attempts in this direction have been made by Boudon (1974), however, that resulted in a simulation model and not in a well-specified mathematical model.

The objective of this paper is to suggest a particular solution to the problem of specifying a theory of the attainment process that conceives of structurally-induced mobility as the source of change in individual attainment. This will involve (1) specifying a model for the structure of inequality, i.e., the distribution of possible attainments, then (2) specifying how vacancies occur and move in this structure and, finally, (3) modeling how change in attainments are brought about by the movement of people along the structurally-induced vacancy chains. These are the main tasks of the paper. The final sections of the paper will outline the relationship between the proposed model of the attainment process, status attainment research, and research on intragenerational mobility.

A number of very strong assumptions will be utilized in deriving the model. These assumptions are necessary to simplify an otherwise very complicated

problem. To some, the resulting model may appear highly unrealistic. That the model provides a very simplified picture of reality will not be denied. However, it does account for important features of observed processes and provides a plausible interpretation of research on attainment and mobility.

The Structure of Inequality

The objective is, as mentioned, to formulate a model for the attainment process, where change is brought about by utilizing opportunities for change of position in a predetermined structure of inequality. The positions will be conceived of as jobs, and these jobs may be characterized by the economic, social and psychological rewards they provide incumbents. It is assumed that only a change in jobs can provide a change in the level of rewards. This is a reasonable assumption with respect to most rewards, but it may appear dubious with respect to earnings. There will be real and inflationary increases in earnings within a job as well as some performance-related variation. These real and inflationary increases will be ignored because they usually do not change a person's relative position. Performance-related variation within jobs will be assumed to be of minor importance. One reason is that major performance differences for people in similar jobs are a source of instability and, hence, likely to result in differentiation of jobs.

Stated differently, the basic assumption is that different people in the same jobs will obtain the same rewards, while the same person will obtain different rewards in different jobs. With this assumption, the structure of inequality is given as the distribution of jobs with respect to status, income and other rewards.² Jobs may be vacant or filled, and people may be employed or unemployed. Hence, the distribution of jobs will not correspond to the distribution of people, although it will be

² No attempt will be made here to explain how the distribution of attainments comes into being. For the purposes of this paper, it is taken as a given. The assumptions stated here correspond to the one made by Thurow (1975) that marginal productivity resides in jobs, not in persons.

roughly similar to the distribution of employed people. For present purposes, this distribution will be assumed stable over time.

In the sequel, it will be assumed that there exists a measure of attainment level similar to the measures of prestige or socioeconomic status so commonly employed in status attainment research. As argued by Goldthorpe and Hope (1972), these measures reflect the "goodness" of occupations not the "prestige" of occupations in the usual sense of the word where the referent is to deference—that is, a relational concept—and not to the distributional concept captured by the Duncan SEI, NORC prestige scores, etc. However, the existing measures are ordinal and, though commonly employed as interval scales, this usage does not change their metric properties. The measure of attainment level assumed here is a ratio-level measure with a well-defined zero point.

The attainment level a person obtains in a job is denoted by y , where y varies from zero to infinity. I shall assume a very simple model for the distribution of y . This model is the exponential distribution with probability density,

$$f(y) = -\beta e^{\beta y} \quad \beta < 0 \quad (1)$$

and distribution function,

$$F(y) = \Pr(y \leq y') = 1 - e^{\beta y'}, \quad (2)$$

The distribution is governed by a single parameter β assumed to be less than zero. It describes a pyramidal structure of inequality in society, where the density of jobs decreases as y increases according to the formula,

$$\frac{df(y)}{dy} = \beta f(y), \quad (3)$$

as (1) is the solution to (3) assuming $f(0) = -\beta$. In other words, the distribution is such that the density is highest at the bottom level of attainment and decreases as y increases by a constant proportion with each small increase in y .

The quantity β may be said to govern the shape of the distribution of attainments. The larger β is in absolute mag-

nitude the more evenly jobs will be distributed. This means that if a person has a job providing a certain level of attainment, say y' , β will determine the proportion of jobs providing a level of attainment higher than y' , as the quantity $\Pr(y > y') = 1 - F(y) = e^{\beta y'}$ will be smaller the larger β is in absolute magnitude. The proportion of jobs that are better than the one currently occupied by a person represents possible opportunities for gains in attainment for this person. As β determines the proportion of jobs that are better jobs, it is one of the two quantities that governs the opportunity structure of a society—the other quantity being the rate at which better jobs become vacant, as I will show in the sequel.

The exponential distribution is the continuous variable analog to the geometric distribution that would apply if attainment was measured as a discrete variable.³ The geometric distribution has been suggested by several as a representation of the structure of inequality (Simon, 1957; Bartholomew, 1972; Svalastoga, 1973; Stinchcombe, 1974). Bartholomew (1972) shows that if this distribution is assumed for an organization, a particularly simple promotion schedule will prevail—a property to be used in this paper.

When evaluating the plausibility of the model (1), it should be noted that the quantity y is a construct. Specifying the relation between y and an observable reward will generate an observable distribution that can be used to validate the exponential model for y . Lydall (1959) has shown that, in the case of the geometric distribution of attainment levels, the Pareto distribution of incomes may be generated assuming that the log of earnings provided by jobs is linearly related to attainment. The argument is easily generalized to continuous y . The distribution function is

$$\Pr(w > w') = ke^{-\alpha \log w'} \quad (4)$$

³ The geometric distribution may be derived assuming that the ratio between the number of jobs at level k (where k is the discrete variable analog to y) is a constant proportion of the number of jobs at level $k-1$, or $n(k)/n(k-1) = s$ where $n(k)$ is the number of jobs at level k and s is a quantity less than one and greater than zero.

where w denotes earnings. Here, $-\alpha$ is a function both of β and the relation between y and earnings. Assuming the validity of the linear relation between $\log w$ and y , equation (4) could be used to evaluate the exponential model using observed earnings distributions.

Pareto proposed the model for income distributions that bears his name from inspection of observed income distributions based on tax returns. At that time, no returns were obtained from the lower portion of the distribution, and equation (4) provided an extremely good fit to the upper tail of the distribution. Pareto promoted equation (4) to a law, but subsequent analysis has shown that it does not fit the lower portion of the income distribution very well, and a number of other distributions will be similar to equation (4) in their tails. In particular, the log normal distribution first suggested by Gibrat (1931) provides a better overall fit.

The problem is that in observed distributions the density increases with increasing income in the lower portions, contrary to equation (4). It is well known that persons out of employment or with only marginal attachment to the labor force dominate in this part of the distribution. Equation (4) would be used here as a model for the distribution of the earnings provided by jobs, not personal incomes, and therefore may be less unrealistic. Further, only the distribution of filled jobs can be observed, while equation (4) would describe the distribution of all jobs whether filled or vacant, when used as a check on equation (1). Hence, it may be argued that a lack of fit is due to the omission of vacant jobs from observed distributions.

A model for observed prestige distributions could be generated assuming a one-to-one relationship between y and prestige (or SEI) scores. This may appear to be a reasonable proposal because of the definition of y presented above. However, none of the measures of prestige or socioeconomic status derived from prestige scores (as the SEI index) will result in distributions that can be used to test equation (1). The reason is that prestige scores as mentioned are inherently ordinal. Hence, they may be subject to any transformation that preserves rank order. Each transforma-

tion will result in a new distribution. The one that is observed using currently used measures therefore is completely arbitrary and cannot be used to validate (1).⁴ Only income distributions can be used, but then it is necessary to further assume the validity of a particular specification of the relation between y and income.

Despite the objections that may be raised, the exponential distribution will be used in the sequel as a model for the distribution of job rewards. It leads to a particularly simple and fruitful model for the attainment process and captures basic features of the structure of inequality. These properties are enough rationale for its use as a start.

The Creation of Opportunities for Growth in Attainment

Having formulated a model for the structure of inequality, the task now is to formulate a model of how opportunities for change in attainment are created in this structure. In the next section, the question of how characteristics of individuals affect their ability to take advantage of these opportunities will be addressed.

The structure of inequality will be assumed stable over time. People enter and exit the structure when they enter and leave the labor force. When people leave the labor force, they leave vacant jobs. These jobs will be filled either by new recruits or by people moving from other jobs into the job vacated. Following White (1971), two types of moves may be conceived of—(1) moves by people from filled jobs to vacant jobs, thereby creating new vacancies to be filled by others already in the system or by people entering the system, and (2) moves by vacancies in the opposite direction of the moves by individuals. Chains of moves by persons start when a person enters the labor force and end with retirement (temporary moves out of the labor force will be ignored). Chains of moves by vacancies start with the creation of a vacancy due to retirement (or the

⁴ In other words, no one knows what the structure of inequality is in society in terms of the "goodness" of jobs, for no one has seen it.

creation of a new job) and end by the elimination of a vacancy by a person from outside the system (or by the elimination of a job). Both people and vacancies move among jobs, but the mobility history of a vacancy is something different from the mobility of people. This section will focus on the mobility of vacancies. In the next section, the mobility of people will be linked to the mobility of vacancies.

When a person moves from one attainment level to another, a vacancy moves in the opposite direction. Upward moves by people in the structure represent increases in attainments and correspond to moves downward by vacancies. Only such moves will be considered. Although upward and horizontal moves by vacancies will take place in empirical systems corresponding to downward and lateral moves by people, they will be ignored here. Assuming persons maximize attainments, this restriction implies that only voluntary moves will be considered.

It will be assumed that persons enter and retire at all levels. It is immediately apparent that if voluntary moves are to take place at all, fewer people should enter than leave at some levels; in this way, vacancies will be created for people at lower levels to take advantage of. In work on mobility in organizations, it is often assumed that everyone enters at the bottom and leaves at the top (Bartholomew, 1972). This is obviously unrealistic for the societal structures of inequality considered here. A more realistic, although very simplifying assumption will be made here. It will be assumed that a proportion of jobs will be vacated due to retirements in each time period—the same at all attainment levels. Further, it will be assumed that some of these vacated jobs will be filled from the outside and some will be filled from below. The proportion to be filled from below presents new promotion opportunities and also will be assumed to constitute a constant proportion at each level. The exception is the bottom level, where all vacancies are filled by persons from the outside.⁵

It is assumed, in other words, that new vacancies not immediately filled by new entrants to the labor market are created at a constant rate for each level of attainment. These vacancies will reflect the addition of new jobs to the economy and/or that each person enters a promotion ladder that covers some, but not all attainment levels. By giving rise to vacancy chains, these vacancies create promotion opportunities in society. There is evidence that most job shifts are voluntary (Sørensen, 1975). Hence, the assumption of new promotion opportunities being created in each time period is reasonable, although the assumption of identical rates of new vacancies at all levels may not be realistic.

With these assumptions, one may calculate the rate at which vacancies arrive at a certain level of attainment. This rate will represent the opportunities for gains in attainments presented to persons who occupy jobs at lower levels of attainment. To do this, some new quantities need to be defined. As before, denote by $f(y)$ the probability density of y . The density of jobs at level y is $n(y) = Nf(y)$ where N is the total number of jobs in the system. Let $h(y)$ denote the rate at which new vacancies to be filled from below or new promotion opportunities are created at level y . Finally, let $m(y)$ denote the number of vacancies arriving at y per unit time.

The number of vacancies arriving at y , that is, $m(y)$ will equal the number of new vacancies created at $y + dy$ plus the number of vacancies arriving at $y + dy$ from attainment levels higher than $y + dy$. The number of vacancies arriving at $y + dy$ is $m(y + dy)$ by the definition of $m(y)$, and the number of vacancies created at $y + dy$ is $h(y + dy)n(y + dy)$. Hence,

$$m(y) = h(y + dy)n(y + dy) + m(y + dy) \quad (5)$$

⁵ Vacancies not immediately filled by new entrants to the labor force will move down according to the formula presented below. The corresponding va-

cancy chains are all terminated at the bottom level by new recruits from the outside. In other words, vacancies not immediately filled from the outside will create vacancy chains that move through the whole structure. The mobility chains of a person take place along these vacancy chains, but only over some part of the structure, as the next section will show.

per unit time.⁶ But since the rate at which new promotion opportunities are created is assumed the same at all levels $h(y) = h$ for all y , (5) can be written as

$$m(y) = hn(y + dy) + m(y + dy). \quad (6)$$

The argument that results in (6) may be used to generate an expression for $m(y + dy)$. This quantity will equal $hn(y + 2dy) + m(y + 2dy)$. Hence (6) may be written as

$$m(y) = hn(y + dy) + hn(y + 2dy) + m(y + 2dy). \quad (7)$$

Further, $m(y + 2dy)$ may be written as a function of the rate at which new promotion opportunities are created at the next higher level and the density of jobs at this level. In this fashion, $m(y)$ eventually may be obtained as h times the total number of jobs at higher levels of attainment. The total number of jobs at higher levels of attainment is obtained by integrating $n(y)$ from y to infinity. Hence,

$$m(y) = h \int_y^\infty n(u) du. \quad (8)$$

But $n(y) = Nf(y)$, and $f(y)$ is defined in (1) as $-\beta e^{\beta y}$. Substituting in (8) gives

$$m(y) = h \int_y^\infty Nf(u) du = hNe^{\beta y}. \quad (9)$$

Equation (9) gives the total number of promotion opportunities available to all incumbents of jobs at level y . To obtain the promotion rate per job, it is necessary to divide by the density of jobs at level y . Denote by $q(y)$ the promotion rate that represents the promotion opportunities an incumbent of a job at level y will be exposed to. This quantity will be

$$q(y) = \frac{m(y)}{n(y)}. \quad (10)$$

But $n(y) = Nf(y)$. Hence, from (9) and (1),

$$q(y) = \frac{hNe^{\beta y}}{N[-e^{\beta y}]} = -\frac{h}{\beta}. \quad (11)$$

It follows that, at all levels of attainment, $q(y)$ will be the same, or $q(y) = q$ for all y . The quantity qdt may be conceived of as a promotion probability for persons at a given attainment level: it is the probability that a person may realize a gain in attainment. The derivation has shown that this quantity is a function of h , the rate at which new promotion opportunities are created, and of β that governs the shape of the distribution by determining the proportion of jobs that provide a higher level of attainment. The result is a direct consequence of assuming an exponential distribution of attainments. If some other distribution was assumed, q would not be independent of y , and a much more complicated analysis would have to be undertaken.

It is important to note that q is defined on jobs not on people. While everyone at a given attainment level is exposed to the same q , they are not equally likely to take advantage of it. The extent to which they are able to take advantage of the opportunities represented by q will be argued in the next section to be a function of individual characteristics such as education, ability and background and will be linked to the amount of time already spent in the labor force.

To avoid a proliferation of symbols, q will be in the sequel be taken as equal to $-1/b$ where $b = \beta/h$ —a function of both the shape of the distribution of jobs and the rate at which new vacancies are created.

The Attainment Process

In a structure of inequality characterized by equation (1), it will be the case that at all levels of attainments everyone will be exposed to the same opportunities for increases in attainment as determined by the quantity q of equation (11). This section will address the question of how individual characteristics

⁶ If attainment were to be considered as a discrete variable and the structure of inequality described by the geometric distribution, the parallel formulation would be $m(k) = h(k+1)n(k+1) + m(k+1)$, where k is the discrete variable analog to y . In other words, the number of vacancies arriving at level k equals the number of new vacancies created at level $k+1$ plus the number of vacancies arriving at $k+1$ from above. The conclusions drawn here using continuous y will also hold in the discrete case.

determine a person's ability to take advantage of the opportunities for growth in attainment given by q .

The individual characteristics relevant for a person's attainment will be said to determine a person's resources. These resources are assumed formed by the time a person enters the labor market, and not subject to further change. This is the exact opposite of the assumption made in human capital theory where it is assumed that a person's level of resources (as expressed by his productivity) is changing over time due to on-the-job training, experience and the like. Such additions to a person's resources are measured in empirical investigations of human capital theory by time spent in the labor force. Here, time spent in a labor force will be a measure of how long persons have been exposed to the mobility regime formulated in the preceding section. No claim for the universal validity of the assumption of no change in resources over time can be made, but neither can such a universal claim be made for the validity of the assumption that all changes in attainment are due to changes in resources. Empirical analysis does not necessarily confirm the latter assumption when time is used as a proxy for growth in resources.

The higher the attainment level of a job, the higher the level of resources needed to gain access to a job. It will be assumed further that for a given level of personal resources, there is an attainment level that is the best a person can hope to obtain. This is the case because the distribution of jobs according to attainment levels is fixed; hence, everyone entering at a certain level has to exit in such a way that the distribution is preserved. A job at the highest attainment level possible for given resources should not be left voluntarily by a person, for there is then no gain to be made. Not all people occupy this level, as voluntary moves are assumed possible in the system as defined above because of the creation of new promotion opportunities at each level of attainment. Some people, therefore, are in jobs that provide them with lower attainments than they may hope to obtain. Since every move voluntarily undertaken by a person will produce a gain in attainment, those who

have just entered the labor force will have the lowest attainment relative to their resources. The longer the time a person has spent in the labor force, the more likely it is that the person has the best job (s)he can hope to obtain. Hence a person's ability to take advantage of a vacancy at a higher attainment level will depend on the amount of time spent in the labor force. Time in the labor force, in turn, summarizes all information on the relation between a person's resources and his/her current attainment.

Denote by $r(y,t)dt$ the probability that a person at attainment level y and having spent t years in the labor force will change jobs; i.e., take advantage of a vacancy arriving in dt at his/her current level of attainment. It must be the case that for all people at y , the individual $r(y,t)$'s must sum to the overall rate at which vacancies arrive at y or $q(y)$. The $r(y,t)$'s of persons at y differ only with respect to t ; hence,

$$q(y) = \int_0^{\infty} r(y,t)dt \quad (12)$$

where the integration runs over values of t so that $t \rightarrow \infty$ as the rate of leaving the current attainment level approaches zero for people with attainments commensurate with their resources. It was established in the preceding section that $q(y)$ is a constant and equal to $-1/b$. Hence, (12) implies that

$$\int_0^{\infty} r(y,t)dt = -\frac{1}{b}. \quad (13)$$

The index y may be dropped from $r(y,t)$ since the rate of shift is the same at all attainment levels. The specification of $r(t)$ that is a monotonic function and satisfies (13) is

$$r(t) = e^{bt}. \quad (14)$$

Since $b = \beta/h$, it has been shown that $r(t)$, the rate at which an individual with t years of experience moves to a higher level of job rewards, depends on: (1) h —the rate at which new vacancies are created, (2) β —the parameter that governs the shape of the distribution of attainments and (3) t —the amount of time spent in the labor force.

A person moves to a higher level of attainment through a voluntary job shift. The rate, $r(t)$, of voluntary shifts integrated over t will give the number of shifts a person has undertaken by time t . Denote this quantity $v(t)$, and define it as

$$\begin{aligned} v(t) &= \int_0^t r(u) du \\ &= \frac{1}{b} (e^{bt} - 1) \end{aligned} \quad (15)$$

with a maximum value $v(\infty) = -\frac{1}{b}$, that is, the total number of shifts a person will undertake in his/her lifetime. This quantity can be used to derive the gains in attainments obtained by a person. Denote by $y(0)$ the level of attainment for a person at entry into the labor force, by $y(t)$ the level obtained by time t , and by $y(m)$ the maximum level of attainment possible. The total growth possible is then $y(m) - y(0)$. At each job shift, a person will realize a fraction Δy of this gain. On the average, the gain will be

$$\Delta y = \frac{y(m) - y(0)}{v(\infty)} \quad (16)$$

It will be the case that the level of attainment by time t will be equal to the level at entry plus the gain realized up to this point, or

$$y(t) = y(0) + v(t)\Delta y. \quad (17)$$

Substituting equations (15) and (16) in (17) will give

$$y(t) = y(0) + \left[\frac{1}{b} (e^{bt} - 1) \right] [-b(y(m) - y(0))]. \quad (18)$$

Differentiating gives

$$\begin{aligned} \frac{dy(t)}{dt} &= [-be^{bt}][y(m) - y(0)] \\ &= -b[y(m) - y(t)]. \end{aligned} \quad (19)$$

This is finally the model for change in attainment that obtains in a structure of inequality where mobility takes place in the manner described here.

A person's resources will determine the level $y(m)$ that (s)he eventually will obtain. However, the value of $y(m)$ for the same level of resources will be different in

different opportunity structures, i.e., for different values of b . To reflect this, a slight reformulation of (19) is useful. Define a quantity z through the relation,

$$\frac{dz}{dy(m)} = -b. \quad (20)$$

Let z be defined as a person's resources. It will vary across people but, for each person, be constant over time. From (20) by integration,

$$y(m) = -\frac{z}{b} \quad (21)$$

incorporating the constant of integration into z . Substituting into (19) gives

$$\frac{dy(t)}{dt} = z + by(t). \quad (22)$$

This is the simplest linear differential equation with negative feedback of the dependent variable on itself. The negative feedback has been shown here to be determined by the rate at which new vacancies are created and the shape of the distribution of jobs according to attainment levels.

Equation (22) describes a career line that is concave to the time axis; that is, there will be rapid growth in attainment in the beginning of the career and slower growth later until the attainment reaches the stable level $y(m) = -z/b$. This pattern is found on observed career curves. For an example, see Sørensen (1975:463)⁷

The career line predicted from the model also corresponds to the one predicted from human capital theory. In this theory, the curve is predicted from a pattern of growth in resources where resources grow at a lower rate as people get older, primarily because there is less time left in the labor force in which to recapture costs incurred in acquiring more resources. More specifically, the neo-

⁷ It is shown in Sørensen (1975:463) that the career lines of black males are flatter than those for white males. This presumably reflects the more unfavorable opportunity structure for blacks; that is, $b = \beta/h$ is larger in absolute magnitude for blacks.

classical theory assumes that, at any point in time, the level of attainment is $y(m)$, but the resources, z , change over time in a manner that results in the observed concave career profiles.

Both human capital theory and the theory formulated here predict the same career line. The observed career lines thus do not validate either theory. The objective here was not to prove human capital theory wrong, but to formulate an alternative theory using assumptions that are the opposite assumptions of those used in the economic theory. It would be a poorer theory if it could not account for the same observed career patterns as the human capital theory.

The model developed in this section is of importance both for the interpretation of status attainment research in the tradition created by Blau and Duncan (1967) and for research on intragenerational mobility.

Implications for Status Attainment Research

Research on status attainment usually employs linear equations where the level of attainment, as measured by SEI or prestige scores, is the dependent variable. Characteristics of the individual are employed as independent variables. Typically, they are measures of the respondent's education, father's status, parents' education and other measures of family background. All explanatory variables are then measures of individual characteristics, and no attempt is made to introduce characteristics of the structure of inequality. The model formulated here is derived from consideration of the impact of structural characteristics on growth in attainment, and its parameters are well defined in terms of the various forces that govern attainment processes. The attainment model, therefore, can be used to reinterpret status attainment models and evaluate the appropriateness of the research designs typically employed.

A global measure of resources, z , was used in the derivation of the model above. A formulation of this model that makes it similar to the models employed in status

attainment research is obtained by letting z be a linear function of relevant individual characteristics, or

$$z = c_0 + c_1x_1 + c_2x_2 + \dots + c_nx_n \quad (23)$$

where the x_i variables stand for education, father's status, parents' education, etc. The coefficients to the x_i variables represent the contribution of these variables to the overall level of resources. In status attainment research, as here, these resources are assumed constant over time, although status attainment research has never been explicit about such assumptions. With this expression for z , the model for the process of attainment becomes

$$\frac{dy(t)}{dt} = c_0 + by(t) + c_1x_1 + c_2x_2 + \dots + c_nx_n \quad (24)$$

This model has the solution

$$y(t) = \frac{c_0}{b} (e^{bt} - 1) + e^{bt}y(0) + \frac{c_1}{b} (e^{bt} - 1)x_1 + \frac{c_2}{b} (e^{bt} - 1)x_2 + \dots + \frac{c_n}{b} (e^{bt} - 1)x_n \quad (25)$$

This is one of the most important equations estimated, in status attainment research, as it relates current status of a respondent to the status of first job and individual resources. Typically, this equation is estimated by pooling all respondents on cross-sectional data.

The use of cross-sectional data assumes that the process is in equilibrium. In terms of the model, this means that $dy(t)/dt = 0$, and the level of achievement is

$$y(m) = -\frac{c_0}{b} - \frac{c_1}{b}x_1 - \frac{c_2}{b}x_2 - \dots - \frac{c_n}{b}x_n \quad (26)$$

where $y(0)$ does not appear. Thus, if the assumption of equilibrium is valid, the typical model that includes the status of first job is misspecified. However, the assumption of the process being in equilibrium is generally not valid for representative samples of a population. Hence, observed coefficients to the x_i variables will be some function of

$$d_1 = \frac{c_1}{b} (e^{bt} - 1). \quad (27)$$

This means that the observed coefficients will be a function of (1) the amount of time respondents have spent in the labor force, (2) the quantity b that measures the opportunities for growth in attainment as determined by both the rate at which vacancies are created and by the shape of the distribution of jobs by attainment level and (3) the contribution c_1 of the variable in question to a person's overall level of resources.

Equation (24) can be used to estimate the various parameters if applied to over-time data (see Coleman, 1968; Sørensen, 1977 for details); but when all respondents are pooled in a cross-sectional design, such identification is not possible.

It should be noted that the dependency of d_1 on both time and b is such that the older the respondent and the more favorable the opportunity structure, the larger the magnitude of the effects of x_1 variables. Therefore, one should expect that the effect of a major determinant of resources such as education should have an observed effect on status that increases with time in the labor force. Such a pattern can indeed be found on life-history data (Sørensen, 1977). Further, it is expected that if blacks are assumed to be exposed to a more unfavorable opportunity structure than whites, observed status returns to education should be lower for blacks than for whites. This pattern has been found repeatedly.

Research on the process of stratification and status attainment originated in intergenerational mobility research where the objective of comparing equality of opportunity in different societies and over time has always been a dominant one. Such comparisons could, in the framework of linear models, be carried out by comparing the effect of father's status on son's status observed in different societies or at different time periods. This would amount to estimating the equation

$$y = d_0 + d_1 x_1 \quad (28)$$

where y is the observed status of sons and x_1 is the status of fathers, and comparing d_1 over time or across societies. In the framework of the model proposed here,

this means estimating the equilibrium equation (26) omitting other x_1 variables, so that $d_1 = -c_1/b$.

The coefficient d_1 as a measure of equality of opportunity will confound variation in the contribution of father's status to a son's overall level of resources (c_1) and variation in the opportunity structure (b). Different implications for our understanding of societies depend on whether the contribution of father's status to resources or the opportunity structure are responsible for the variation. In particular, it can be noted that in two societies where parental status is equally important for a person's resources, the society with the most favorable opportunity structure will show the most inequality of opportunity because b will be closer to zero and, hence, d_1 will be larger in absolute magnitude.

Implications for Models of Intragenerational Mobility

Social mobility always has attracted mathematical sociologists as a phenomenon that should lend itself to modeling using stochastic process models. The inherently stochastic nature of the process and the use of discrete occupational categories seem to call for a stochastic process model. Furthermore, mobility tables—showing the number of persons moving among occupations—are readily converted into estimates of transition probabilities of a Markov chain by dividing the row totals into the cell frequencies.

All attempts at testing the simple Markov chain on mobility data, however, has shown that this model does not account for observed movements (for an early example, see Blumen et al., 1955). Numerous reasons have been given for the failure of the model—heterogeneity in the parameters (McFarland, 1970; Spilerman, 1972), duration-specific transitions or cumulative inertia (McGinnis, 1968; Tuma, 1976) and age dependency in the parameters (Mayer, 1972; Sørensen, 1972). The resulting modifications of the Markov Model usually improve the fit of the model. However, the improved fit does not necessarily indicate the validity

of the proposal. Heterogeneity will result in apparent nonstationarity, and vice versa, so that attempts to remedy either problem will improve the fit but not necessarily indicate the true source of failure in the model. Similarly, duration-specific rates and age dependency are difficult to tell apart since age and durations in jobs are highly correlated. Most of the proposals for improving the Markov Model are *ad hoc* proposals that are not based on an explicit theory of the mobility process. Hence, it is not possible to choose among the proposals on theoretical grounds either.

The model for the attainment process proposed here indicates a specific modification of the simple Markov Model. This modification has been described in another paper (Sørensen, 1975), where an empirical analysis using the model is also carried out. The main result shall be summarized here briefly.

The simple Markov Model can be written (cf. Singer and Spilerman, 1976)

$$P(t) = P(0)e^{\lambda(M-I)t} \quad (29)$$

where $P(t)$ is a vector giving the distribution of people according to job categories (say occupations) by time t . The matrix M has elements m_{ij} that give the probabilities of moving from category i to category j , given that a person is in state i ; and I is the identity matrix.

The parameter λ , a scalar, is the rate of job shifts that is assumed constant over time in the simple model. In a system governed by the mobility regime described in this paper, λ will be dependent on time in the labor force, as λ corresponds to the quantity $r(t)$ defined in equation (14). This suggests that a reformulation of equation (29) where λ is dependent on time will be a more adequate representation of the intragenerational mobility process. A particularly simple representation is obtained by redefining time to take into account the decline in $\lambda(t)$ with time.

The desired redefinition of time should be such that, in the new time scale, the rate of job shift is constant over time; that is, job shifts follow a Poisson process. It still may be the case that the rate of shift will show variation among people; that is,

heterogeneity will be present. However, removing the nonstationarity also will remove much of the apparent heterogeneity. In addition, the decline in the rate of job shift by time in the labor force was shown above to be generated by a reduction of the discrepancy between current attainment and the maximum attainment to be obtained. The latter quantity is determined by a person's resources. Hence, the time dependency in the rate indirectly captures important sources of variation among people.

The redefinition of time is obtained easily by defining a new time scale as the number of opportunities for shifts a person has encountered after t years in the labor force. The number of opportunities is captured by the quantity $v(t)$ defined in equation (15).

Assuming the validity of the model, the rate of shift in time scale $v(t)$ will be time independent. Denote this rate of shift λ^* . This quantity, in fact, will be 1, if it is assumed that people only shift to obtain gains in attainment. If voluntary shifts for other purposes are allowed, a value of λ^* different from 1 will be observed.

With this time transformation, the Markov Model can be written

$$P(v) = e^{\lambda^*(M-I)v} \quad (30)$$

assuming $P(0) = I$; and if the time transformation indeed removes time dependency in the rate of shift, a more realistic model is obtained.

A test of the proposed model for the dependency of the rate of job shifts on time in labor force can be obtained using life-history data that give information on the completed durations of each job. The completed durations are the waiting times between events and, if events follow a Poisson process, in $v(t)$ waiting times will be exponentially distributed with a mean that will estimate the inverse of the rate. Transforming the completed observed duration into time scale $v(t)$, therefore, should produce exponentially distributed durations with means independent of time in the labor force. A test of the time transformation using this property was found to be quite satisfactory. A slight departure from the expected pattern could be ex-

plained as resulting from a change in the opportunity structure in the period where these job shifts took place. This change in opportunity structure is reflected in a decrease in the parameter b that governs the time transformation. It was shown further that the change in opportunity structure favored whites more than blacks (Sørensen, 1975:458).

The proposed attainment model not only leads to a more empirically adequate stochastic model of mobility but also points to substantively meaningful analysis. The results summarized here, particularly the successful removal of time dependency in rates of shift using the model, in turn lend support to the model proposed in this paper.

Conclusion

This paper has proposed a model for the process of attaining income, status and other job rewards. The structure of inequality—that is, the distribution of jobs according to attainments—is assumed fixed and not subject to change due to variation in the distribution of personal resources (family background, education, ability) relevant for getting access to jobs. A simple exponential model is assumed for the attainment distribution. In this structure, new vacancies are created in each period of time, and these vacancies represent opportunities for growth in individual attainment. The mobility regime that prevails in such a structure—where persons are entering and leaving the labor force at all attainment levels—was shown to be particularly simple. It is further assumed that an individual's ability to take advantage of the opportunities for attainment gains is dependent on his/her current attainment relative to the maximum level of attainment (s)he will be able to obtain given his/her resources. These resources are assumed to remain unchanged after entry into the labor force. From these assumptions, a simple linear differential equation model is derived for change in achievement over time.

The theory proposed here is derived explicitly on assumptions that are contrary to those used in human capital theory. There, change in attainments after

entry into the labor market are assumed to reflect changes in personal resources due to on-the-job training, experience and the like. In human capital theory, a competitive market for skills is assumed to exist with no imperfections producing individual attainment increases without increases in resources (productivity). It is a consequence of this theory that the structure of inequality will reflect the distribution of individual resources as the supply of people at various levels of resources will affect the returns (attainments) obtained, assuming a given demand schedule. Changes in the distribution of resources thus will change the structure of inequality.

Assuming attainment changes are produced by the creation of vacancies in a predetermined structure of inequality is consistent with the observed stability of the income distribution since World War II despite a marked change in the distribution of education—a stability that is contrary to the implications of human capital theory. In the framework proposed here, changes in the distribution of resources are assumed not to affect the structure of inequality, though resources are crucial for individual attainment. Changes in the distribution of education presumably would change the relative importance of education among the various attributes relevant for attainment, but not the distribution of rewards provided by jobs.

The purpose of the paper has, however, not been to prove human capital theory wrong. Both processes may operate simultaneously, and labor markets may be segmented according to whether one or the other process is dominant. The empirical identification of which mechanism prevails where is a major research task for which the theory proposed here only represents an alternative point of departure to the economic theory.

COMMENTS

CITY NONDIFFERENCES REVISITED*

(COMMENT ON STOLZENBERG AND
D'AMICO, ASR DECEMBER, 1977)

Stolzenberg and D'Amico's paper in this issue of the *Review* contains errors of conceptualization and methodology. In our opinion, the errors are sufficient to undermine the validity of their conclusions.

I.

Stolzenberg and D'Amico (hereafter SD) review the principal studies regarding the relationship between black occupational status and city characteristics. They note Turner's (1951) conclusion about the relevance of industry structure, Glenn's (1963; 1964) thesis concerning the "overflow" of blacks into upper status occupations where they constitute a large portion in the population, and Cutright's (1965) contention that whites also benefit in occupational standing from residing in a large proportion black community. Finally, they comment on our (Spilerman and Miller, 1976) attempt to assess the importance of these and related community factors for black and white status.

The thrust of SD's argument is to dismiss the foregoing studies as being concerned with a "trivial" amount of variation: "[F]or about three decades, the sociological literature has indicated that there is substantial intercity variation in the race-occupation relationship. . . . In a word, we find that variation in the race-occupation relationship between large metropolitan areas is trivial" (p. 938).¹ Central to their argument is a demonstration that the three-way interaction between race, occupation and city in a log-linear formulation is very small. In particular, SD report that in the non-South² the Index of Dissimilarity between the

observed data and a model based on all two-way interactions is 1.1 percent; also, the amount of variation (X^2) explained by the three-way interaction is only 2.1 percent (7.0 percent in a second formulation). From such results, they conclude that the "intercity variation in occupational differences between the races is not sufficiently important to justify sustained empirical analysis or theoretical explanation" (p. 939).

The error in SD's argument results from equating the three-way interaction in a log-linear model with the propositions in the literature concerning city effects on the occupational standings of the races. The log-linear model, as employed by SD, generates a particular decomposition of the variation into main effects and interactions of different orders. However, the theoretical explanations which SD address—and dismiss—cannot be simply associated with an interaction term of a given order.

To convey the import of this remark, we present hypothetical data in Table 1 such as would result from an "overflow" process as described by Blalock (1957), Glenn (1963; 1964), Cutright (1965) and Spilerman and Miller (1976:2).³ The four cities in the table differ by percentage black, ranging from 28 percent to 75 percent. In city 1, with the smallest black population, all blacks are confined to the lowest occupational category.⁴ In larger percentage black communities, their range of occupa-

analysis of southern SMSAs as well. Similarly, we do not discuss SD's results concerning sex effects because our own research has been limited to males. Our criticisms of methodology, however, apply to this portion of their analysis as well.

³ Glenn (1964:43) writes, "[W]here a large percentage of all workers are Negro . . . [Negroes may] 'overflow' into jobs of intermediate desirability. How 'overflow' could produce a direct relationship between Negro occupational status and percentage Negro can more easily be visualized if one imagines discrimination so complete that all Negro workers are kept below white workers." In summarizing this literature, we noted that white status would be raised because the upper-level positions relinquished to blacks would come, to a disproportionate extent, from the lower strata of this occupational category (Spilerman and Miller 1976:2).

⁴ To facilitate convergence of the ECTA program, each cell in Table 1 contains at least the numerical value 5.

*We are indebted to Robert Hauser and Hal H. Winsborough for comments on an earlier draft.

¹ Unless indicated otherwise, quotations are from Stolzenberg and D'Amico's paper in this issue of the *Review*. Our own study (Spilerman and Miller, 1976), upon which SD base much of their analysis, is unpublished at this writing. Manuscript page numbers are therefore reported when that study is cited.

² Because our study (1976) uses data from the non-South, we discuss figures from only that region. Our comments, however, are applicable to SD's

Table 1. Data Illustrative of the "Overflow" Thesis,^a Four Cities

tional options is improved; in city 4, 72 percent of blacks are employed above the lowest occupational rung. This situation, then, is descriptive of the outcome one would expect from a process in which blacks overflow into upper status positions where they constitute a large proportion in the population and relieve whites for even higher status employment.

The validity of the "overflow" thesis is not at issue in this comment; indeed, in our study (1976) we concluded that the effect on black occupational standing is quite small. What is of concern is the ability of SD's formulation to capture the overflow process *when it clearly operates*. To investigate this matter, we performed a log-linear analysis on the data in Table 1, identical to SD's analysis in their Table 1. Our results are similar to SD's findings: the Index of Dissimilarity between the original data and a model containing all two-way interactions equals 1.1 percent. Further, as reported in Table 2, the proportion of X^2 explained by the three-way interaction equals 2.4 percent according to SD's first formulation (CS_1/CS_1),⁵ and 2.8 percent according to their second formulation (CS_2/CS_2). Following SD's reasoning, the variation to be explained is "trivial," hardly worthy of "sustained empirical analysis or theoretical explanation." *Yet, our data were constructed to incorporate a massive "overflow" process.* The reason for this anomaly is that the thesis at issue operates principally through the two-way interactions. SD are incorrect in believing that its import can be judged by an examination of the three-way interaction alone.

⁵ Despite a claim to the contrary (SD, fn 2), the only substantively meaningful baseline model is their second, (Race, SMSA), (SMSA, Occupation). The complete independence model faults the three-way interaction for not explaining the distribution of blacks among cities and the distribution of occupations among cities. For a correct formulation of an identical type of problem, see Hauser et al. (1975:281-4).

It is the case more generally that the hypotheses of city effects on the occupational standings of the races, which SD associate solely with the three-way interaction (and dismiss because this interaction is small), cut across interactions of a particular order in the log-linear formulation. What this literature is about is not narrowly the size of the three-way interaction, but whether it matters in occupational standing for a black man—or a white man—to reside in a community with a particular-sized percentage black population, type of industry structure, or occupational distribution. A large three-way interaction is one way that these factors can be material, but not the only way.

Rather, low-order interactions and main effects tend to be implicated, and this fact is recognized in the literature cited by SD.⁶ Nor are low-order interactions uninteresting for the purpose of theory. Indeed, even were the log-linear analysis to involve primarily main effects, the operative mechanism may be different for each racial group. (An example concerns the impact of proportion in manufacturing on black and white occupational standing. Both groups benefit from a manufacturing concentration, though the causal process involved is different for each [Spilerman and Miller, 1976: Table 2].) Such matters are pertinent to

⁶ In our study (1976), we constructed *separate* models of the determination of black status and white status in order to ascertain the extent to which particular community characteristics affect the standing of each racial group. By this formulation, we were able to identify variables which advantage blacks and whites for identical reasons, variables which advantage both but through different mechanisms, and variables which advantage one racial group but not the other. Also, see Glenn (1963:444) on the reasonableness of assuming an absence of intercity variation in discrimination by whites (i.e., a small three-way interaction) when assessing the impact of city characteristics on the occupational standings of the races.

policy formulation and, in our opinion, a proper concern of theory.

We wish to emphasize that it is not our intention to denigrate the value of a log-linear formulation of these issues. Different methodologies provide alternative perspectives and can lead to greater balance in the understanding of a social process. For this reason, in our study (1976), we employed two conceptual formulations and three index breakpoints to assess the sensitivity of our conclusions to method. With respect to a log-linear formulation, it would be useful to know the extent to which the various explanations in the literature operate through particular main effects, two-way interactions, and the three-way term. SD, however, do not address this important issue and, as we have documented, they have incorrectly associated propositions about city differences in the occupational standings of the races with the three-way interaction.⁷

II.

Having dismissed past research findings, SD ask, "But how do we reconcile the gross differences between our conclusions and theirs" (p. 945). In answering this question, SD commit a second error, this time of a more narrowly methodological kind. SD report that the correlations among the four components of the log of Turner's index all exceed .92. They continue, "Thus, once one knows the number of white men and the number of black men in the ECLF of an SMSA, all the components of the

Turner index are also known. In plain English, this means that city differences in the race-occupation relationship are so small that one can accurately calculate the Turner index for an SMSA merely by knowing the numbers of white and black men in the SMSA's labor force" (p. 945).

Not quite. In Table 3, we present three columns of figures. Think of the first column as containing the number of black men (N_T) in the ECLF of each of ten cities; think of the second column as containing the number of black men in upper status occupations (N_U) in the cities. These data were constructed to illustrate a statistical point, but they are not unreasonable as a description of our cities, although the N s are scaled down for convenience. In particular, the ECLFs in our 1960 Census sample of SMSAs vary in size from 26,000 to 2.96 million, a range of 1 to 113; the corresponding range in black ECLF is even larger, 1 to 285. Thus, the illustrative data do not even exploit the full range of population sizes in the real data. Note, now, that the correlation between $\log N_T$ and $\log N_U$ is very high, .998. In this circumstance, according to SD, "the number of black men in 'good' occupations in an SMSA can be predicted almost exactly from the number of black males in the ECLF of the SMSA" (p. 945).

Now consider a second set of cities with the same total black population figures (column 1), but in which the number of blacks in upper status positions in each city differs from before by exactly 20 percent. Further, we assume that the 20 percent differences are distributed among cities in a manner which greatly reduces the correlation between $\log N_T$ and $\log N_U$ (where N_U is the new number of blacks in upper status occupations), namely the 20-percent changes alternate between an increase and a decrease running over the values in column 2.⁸

⁷ SD's conceptual error is most apparent from the following quote: "To assert that there is intercity variation in racial differences in occupational distribution is equivalent to asserting that . . . if one cross-tabulated workers' race by their occupation by their city of residence, one would observe a three-way interaction" (p. 939). Yet in Table 1, there is considerable intercity variation in racial differences in occupational distribution but only a modest three-way interaction.

⁸ We simulated 20 assignments of plus and minus 20-percent changes in values of N_U among the cities. In five instances, the resulting correlation with column (1) was less than .990, the lowest being .984.

Table 3. Hypothetical Data on Number of Blacks in the ECLF and in Upper Status Occupations in Two Sets of Cities*

City	(1) N_T	(2) N_u	(3) N_{-u}
1	1000	400	480
2	1900	900	720
3	3900	2000	2400
4	6800	4000	3200
5	11000	6000	7200
6	19000	10000	8000
7	28000	13500	16200
8	41000	20000	16000
9	60000	28000	33600
10	89000	42000	33600

* $r(\log N_T, \log N_u) = .998$ (first set of cities). The entries in column (3) were obtained from the corresponding entries in column (2) by increasing or decreasing each value by 20 percent, with the changes alternating in sign. $r(\log N_T, \log N_{-u}) = .990$ (second set of cities).

The resulting figures for N_{-u} are reported in column 3, and the correlation between these entries and those in column 1 equals .990. Thus, we find that a very high correlation between total black population (column 1) and number of upper status blacks is compatible with two very different sets of figures for number of upper status blacks.⁹ Further, corresponding to each 20-percent change we introduced, there is a 20-percent change in each value of N_u/N_T (a principal component of Turner's index), and in Turner's index itself if we assume constancy of the white occupational distribution. In short, SD's claim about predictability of the components of Turner's index from a very high correlation with an ECLF term is in error.

The reason why the correlation between $\log N_T$ and $\log N_u$ is unresponsive to rather substantial changes in the values of the second term is because the ranges in the population figures are very large. In this circumstance, there is considerable room for variation in the individual entries without the correlation being significantly affected. Indeed, it is precisely in this circumstance that standardization is called for. We do not, for example, compare the number of crimes in Madison, Wisconsin with those in Chicago. Instead, we divide by the population at risk and compare crime rates in the two cities. The components of Turner's index used in our analysis (1976)—proportion

of blacks in upper status occupations¹⁰ and proportion of whites in upper status occupations—are rates of exactly this sort, designed to net out the effect of population differences in communities of very different sizes so that sociologically more interesting phenomena can be studied.¹¹

III.

We prefer to conclude on a substantive note. What are some of the city effects on the occupational standings of the races? Based on our causal model (1976: Table 6, 29–32), we find that if a black man were to change cities in a way such that there results a one-standard-deviation increase in the manufacturing proportion, he would find himself in a community in which the occupational standing of blacks is 9.7 percent higher than in the city he left

¹⁰ It is not the case that one can simply replace this ratio formulation by a regression of N_u on N_T (and other variables) as the error term in such a regression will be heteroscedastic. What is the remedy? Divide each term in the equation by N_T ; i.e., create the ratio that we use (Johnston 1963:207–11). Additional comments on the use of ratio variables for the problem we address may be found in our study.

¹¹ Turner's index is a useful measure, though not without its faults. In particular, it is insensitive to distributional differences except at the breakpoint between upper and lower status occupations. To overcome this drawback, we (1976) used multiple cutting points. The fact that Turner's index is responsive to low order interactions and main effects is not a disadvantage for our purposes, since such effects are part of the phenomenon under study. The Index of Dissimilarity—as well as the log-linear model formulated by SD—have a drawback of a different sort: they are insensitive to the hierarchical nature of status.

Because these cases involved irregular patterns of change and because the correlations are not very different, we report the regular pattern in the text.

⁹ Indeed, the correlation remains very high even under a greater manipulation. If a 40 percent change is made to each entry of column (2)—alternating an increase with a decrease—the resulting correlation with column (1) (logged values) is .959.

(Turner's index breakpoint). If he were to migrate to an SMSA larger by one standard deviation in population size, he would be in a community in which 29 percent more blacks are employed in white-collar occupations. In each case, the percentage improvement in white status is negligible.

These are not "trivial" differences with respect to individual opportunity, and the purpose of our analysis was to make clear the mechanisms by which city characteristics influence the occupational standing of blacks. That this is not simply a function of the size of the three-way interaction is evident from our example (Table 1). Despite a small three-way interaction, the occupational prospects of a black man would be considerably better in city 4 than in city 1. Moreover, the operative process is one that we consider to be theoretically interesting.

As a final remark, it is worth clarifying what has been the central research issue in the 30 years of literature referenced by Stolzenberg and D'Amico. The monolithic nature of prejudice and discrimination was well understood by Turner, Cutright, and Glenn. Consider, for example, Glenn's (1963:44) statement: "It is likely that the relative size of the Negro population varies considerably more by locality than does discrimination; therefore, to assume discrimination to be a constant . . . is probably a justifiable simplification of reality." The problem these researchers faced was how to study a phenomenon characterized by a constant! The strategy they adopted was to focus on the *consequences* of monolithic prejudice and discrimination under different structural conditions; i.e., in communities with different characteristics.¹²

We agree with Tukey (1977:72): "Models can—and will—get us in deep trouble if we expect them to tell us what the unique proper questions are."

REPLY TO SPILERMAN AND MILLER

The objections that Spilerman and Miller (S&M) raise in their comment are partly the result of misreadings of the Stolzenberg-D'Amico (S&DA) paper and partly the result of disagreement over methodological and theoretical issues. I address their points in the order in which they raise them.

(1) In the third paragraph of their comment, S&M state that we base our argument on "the amount of variation (X^2) explained by the three-way interaction." This is a misreading of our argument which we took pains to prevent. In particular, we wrote (p. 942):

it is crucial to understand that we are *not* attacking the use of "city" as an independent variable on the ground that it does not explain much variance. Rather, we argue that intercity variation in the race-occupation relationship makes a poor *dependent* variable because it has so little variance to be explained. (*italics in original*).

(2) In their next paragraph, S&M object that:

The log-linear model, as employed by SD, generates a particular decomposition of the variation into main effects and interactions of different orders. However, the theoretical explanations which SD address—and dismiss—cannot be simply associated with an interaction term of a given order.

Here S&M make two errors. First, although they agree that the three-way interaction is small, they do not perceive the consequences of this finding for studies of racial occupational

differentiation. And second, they seem to think that there is something odd or unusual about the "particular" decomposition of covariation (not variation!) generated by the log-linear method. These are the most serious errors in the S&M comment, and I now deal with them.

The consequences of finding a negligible triple interaction term. Our finding of a negligible triple interaction between SMSA, race and occupations has two key implications:

(a) The race-occupation relationship does not vary substantially across SMSAs; the race-SMSA relationship does not vary substantially across occupations; and the occupation-SMSA relationship for whites does not differ materially from the occupation-SMSA relationship for blacks. (b) The occupational distributions of blacks and whites in different cities can be reproduced with tolerable accuracy from the three pair-wise relationships among city, race and occupation. Implication (a) means that stratifying an analysis of the race-occupation relationship according to city of residence will, at best, add *no* information to one's findings, except possibly in the case of anomalous SMSAs. The literature which we criticize is first and foremost a set of stratified analyses in which a summary measure of the race-occupation relationship is computed in each SMSA, and then this measure is related to other characteristics of the SMSA. (Spilerman and Miller's paper is a new variation on this methodology, but not terribly different—they stratify by SMSA separate analyses of white and black occupational achievement.) Implication (b) means that once one has understood the pair-wise relationship between occupation and race, the pair-wise relationship between race and SMSA and the pair-wise relationship between SMSA and occupation, one has understood *implicitly* the occupational distribution of blacks and whites *by SMSA*. Thus, *there is no need to clutter up analyses of the two-way race-occupation relationship by treating this relationship as being possibly different in every SMSA in the country*. To see the advantage of being able to leave "city" out of studies of race effects on occupational achievement, imagine the excruciating complexity involved if Duncan (1968) had stratified his occupational achievement equations by SMSA. Given these implications and lacking any reason to clutter up two-way relationships with extraneous third variables, we suggest that research will be easier, that theory will be more parsimonious and that no damage will be done if efforts are directed toward understanding the three pair-wise relationships among city, race and occupation rather than toward understanding city differences in racial occupa-

tional patterns. In practice, this means that analyses of the pair-wise relationships are sufficient and that one need not perform ecological studies using Turner's index, the index of dissimilarity or other, more complicated aggregate measures. This implication is the very heart of the Stolzenberg-D'Amico paper.

The log-linear decomposition. The decomposition of covariation into main effects and interactions in the log-linear hierarchical model is neither peculiar, nor unusual nor inconsistent with the simplicity-seeking aims of theory construction. Indeed, this decomposition is directly analogous to the decomposition obtained for continuous variables using the analysis of covariance. In most applications, both covariance analysis and log-linear analysis seek simplicity, starting with low-order effects and then adding higher-order interactions as necessary, just as theory-building strategies generally suggest starting with the simplest possible model and complicating it only as necessary. One *could* have theories that are more complicated than necessary, just as one could build models which are composed only of high-order interactions, but the purpose of science is to simplify rather than to complicate, and so simplicity is preferred to complexity, other things being equal. So while it can be distressing to see a complicated theory cut apart by Occam's Razor, the surgery is therapeutic.

At this point it seems relevant to mention a covariance-analytic study of city effects on occupational attainment, which is reported briefly in Mueller (1974). Following Hauser's (1973) methodology, and using Blau and Duncan's OCG data, Mueller found only negligible additive and interactive effects of "city" on occupational attainment. His dissertation also reports an absence of significant interactions between "city" and the effects of race on occupational achievement.

Thus, S&M's most important point—that we have used an inappropriate decomposition of the SMSA-race-occupation relationship—is neither correct in strictly statistical terms, nor consistent with the findings of previous research based on covariance analysis, nor consonant with the simplicity-seeking goals of theory construction.

(3) S&M complain that the log-linear method is insensitive to "overflow" effects. Their support for this complaint is a log-linear analysis of data which they have invented for the purpose of supporting their argument; but I think that they are quibbling here, since they themselves conclude that "overflow" effects in the real world are "quite small" (p. 980).

(4) S&M object that we have missed some-

thing essential in the literature which we criticize:

What this literature is about is not narrowly the size of the three-way interaction, *but whether it matters in occupational standing for a black man—or a white man—to reside in a community with a particular sized percentage black population, type of industry structure, or occupational distribution.* (p. 980, italics mine)

In inviting us to make this interpretation of these studies, S&M invite us to commit the ecological fallacy of making inferences about individual-level occupational achievement from aggregate-level analyses. Mueller's individual-level analysis discussed above avoids this ecological fallacy and is entirely consistent with the argument that racial differences in the occupational attainment process do not vary substantially across cities. More directly, our analysis is an individual level analysis *without problems of ecological correlation* (it cross-classifies men by SMSA, race and occupation). The log-linear triple interaction parameters are directly interpretable as effects of living in a particular city on the black-white difference in the (log) probability of being employed in a given occupation (see Goodman, 1970:228). The chi-square statistics and measures of cases misclassified presented by us indicate that these probability effects can be ignored without doing violence to the observed race-by-occupation-by-SMSA distribution of men.

(5) Next, S&M use hypothetical data to illustrate their argument that "In short, SD's claim about predictability of the components of Turner's index from a very high correlation with an ECLF term is in error." Here, S&M have provided a dramatic, if unnecessary illustration of two well-known properties of regression models. The first point they illustrate is that there are outliers (deviant cases) in regression analysis. We anticipated that there would be outliers, and we speculated about their causes:

We suspect that urban areas which are small enough to have economies dominated by a single firm or a single industry may, as a consequence, have an occupational structure which is marked by the peculiarities of that firm's or that industry's hiring, firing and promotional practices. If these peculiarities include unusually high or low amounts of discrimination, or if they merely create unusual racial differences in occupational distribution without being atypically discriminatory, then places dominated by a single industry or firm will also tend to manifest atypical race-occupation relationships.

The second well-known property of regression which S&M illustrate here is that focusing

only on the deviant cases is likely to blur one's view of the processes affecting the vast majority of cases in the distribution. Spilerman and Miller might have used the standard error of estimate to get a more representative measure of the extent to which the components of the Turner index are accurately estimated from the numbers of white and black men in the experienced civilian labor force (ECLF) of an SMSA.

Where Y is regressed on X , the standard error of estimate is the standard deviation of the difference between the observed values of Y and the values of Y predicted by the regression equation. Thus, where Y is the number of white men in "good" occupations in an SMSA and X is the number of white men in the ECLF of the SMSA, we regress $\log_e Y$ on $\log_e X$, obtaining the equation

$$\log_e Y = a + b (\log_e X) + u \quad (1)$$

where a is the constant term and u is the residual. Using data from non-Southern SMSAs, we found this regression to have an R^2 of .99954 (Stolzenberg and D'Amico, 1977:fn. 6). The standard error of estimate (which is the standard deviation of u) is .02027. Exponentiating both sides of the equation yields

$$Y = e^a X^b e^u, \quad (2)$$

where e is the base of the natural logarithm. Since u is unobservable and has a mean of zero, we would ignore it in making estimates of Y from values of X , using equation (3) below. The circumflex indicates an estimate:

$$\hat{Y} = e^a X^b. \quad (3)$$

Dividing Y by \hat{Y} provides a percentage measure of the inaccuracy of the estimate \hat{Y} . Substituting from (2) and (3), we get

$$\frac{Y}{\hat{Y}} = \frac{e^a X^b e^u}{e^a X^b}. \quad (4)$$

Cancelling terms $Y/\hat{Y} = e^u$. Thus, when u is within one standard deviation of its mean, Y and \hat{Y} differ by only two percent (since $1.02 = e^{0.02027}$). When u is within two standard deviations of its mean, Y and \hat{Y} differ by only four percent ($1.04 = e^{2 \cdot 0.02027}$). Two standard deviations is an unusually large distance from the mean, and four percent seems like a small error. Similar results obtain for estimates of the number of black men in "good" jobs from the size of the black male ECLF. So the components of the Turner index can be computed with acceptable accuracy from the numbers of white and black males in an SMSA's ECLF, contrary to S&M's assertion.

(6) Drawing an analogy to crime statistics, S&M argue for the sensibility of using percentages in analyses of city differences in the race-occupation relationship. I also like the intuitive appeal of percentages, but I recall the well-known difficulties of using percentages or logs of percentages as dependent variables in regression analysis (see Schuessler, 1973; Fuguitt and Lieberman, 1974). The log-linear specification avoids these difficulties with ease (see Goodman, 1970; 1972).

(7) S&M conclude by saying, "We agree with Tukey: 'Models can—and will—get us in deep trouble if we expect them to tell us what the unique proper questions are.' " The quotation is inspiring, but it is irrelevant to the issues at hand. The hypothesis of important city differences in the race-occupation relationship is implicit in some hypotheses which were invented (largely without statistics) about 30 years ago. D'Amico and I looked for the predicted differences and, generally we have found them to be unimportant. So we rejected the hypothesis.

ITEMS (Continued)

grateful to Edmonston, Hannan and Rosenblum for the high quality of their contribution. Second, to the editorial board. Despite the increasing use of special editorial consultants by the ASR, its associate editors continue to play a central role in determining quality. They only contribute about a third of the evaluations used by the ASR, but the associate editors read an average of 36 manuscripts per editor per year while the remaining evaluations are distributed so widely that the typical editorial consultant reads five or fewer manuscripts in a year. Insofar as there is coherence to the ASR's evaluation process, therefore, it lies with the editorial board. I want to thank them for their contributions, particularly the retiring members of the board, Richard A. Berk, Edna Bonacich, Jonathan R. Cole, Robert M. Hauser, George McCall, Jeffery M. Paige and Andrea Tyree. Third, the editorial consultants of the ASR. Increasingly, the ASR has come to rely on more specialized consultants, chosen for their knowledge of specific methods or subjects. Some 300 editorial consultants contribute about two-thirds of the evaluations used by the ASR. No one of them, obviously, has the effect of a member of the editorial board, but in the aggregate they are of great importance to the quality of the *Review*. They are particularly difficult to thank in a genuine way, because essentially one is thanking a list (see page 991). Perhaps the right way to suggest the importance of their contribution is to note the hours spent building and maintaining the two file cabinets containing their names and specialties. Finally, the editorial staff. The life of an editor depends on the ability of the ASR's managing and copy editors. At the Chicago meetings, everyone asked me if I was glad to give it up. Virtually everyone expected me to say "yes" because of the sheer volume of work involved. But the truth is that I give it up with regret, and the reason is that I had a pretty easy time of it because Phyllis Cairns and Harriet Foster made it that way.

■ J. MILTON YINGER (Countercultures and Social Change) is Professor of Sociology at Oberlin College and retiring president of the American Sociological Association. The present paper is a prolegomenon to a theoretical monograph on countercultures. He is also engaged in cross-cultural research on nondoctrinal religious values, writing a paper on assimilation of ethnics, and editing (with George Simpson) a volume of the *Annals of the American Academy of Political and Social Science on American Indians*. His most recent publication (with Kiyoshi Ikeda, Frank Laycock and Stephen Cutler) is a Rose Monograph, *Middle Start: An Experiment in the Educational Enrichment of Young Adolescents* (Cambridge University Press, 1977).

■ GEORGE GONOS ("Situation" versus "Frame") is a candidate for the Ph.D. at Rutgers University. He is currently studying contemporary sociological theory and plans to write in this area.

■ EVIATAR ZERUBAVEL (The Sociology of Time) is Assistant Professor of Psychiatry and Sociology at the University of Pittsburgh. His research interests include the sociology of time, social interaction and interpersonal relations, sociological theory,

and the sociology of knowledge. He is currently involved in a study of decision making in psychiatric treatment and its institutionalized normative regulation. He is completing a book on the temporal structure of social organization based on a study of the socio-temporal patterning of hospital life.

■ GARY G. HAMILTON (Chinese Consumption of Foreign Commodities) is Assistant Professor of Sociology at the University of California, Davis. His current research includes a study of commercial organization in nineteenth- and early twentieth-century China, and a comparative historical investigation of the use of personal staffs as an instrument of rulership.

■ IVAN LIGHT (Numbers Gambling) is Associate Professor of Sociology at the University of California, Los Angeles. His research interests include illegal enterprise, Koreans in Los Angeles, and world urbanization.

■ NORMAN K. DENZIN (The American Liquor Industry) is Professor of Sociology at the University of Illinois, Urbana. He is currently working both on the general theory of social relationships and the theory of criminogenic conduct within larger organizational structures, including scholarly and scientific societies. He is the author of the forthcoming *Becoming a Child: Studies in Language Acquisition, Socialization and the Self* (Jossey-Bass, 1978) and editor of *Studies in Symbolic Interaction* (JAI Press, 1978).

■ STEPHEN R. MARKS (Multiple Roles and Role Strain) is Assistant Professor of Sociology at the University of Maine, Orono. He is currently comparing Durkheim with Abraham Maslow. His basic interest is in links between cultural patterns and humanistic and transpersonal psychology, borrowing in part from research on the nature of altered and expanded states of consciousness.

■ ROSS M. STOLZENBERG (City Differences in Race, Sex, and Occupation) is Assistant Professor of Sociology at the University of Illinois, Urbana. He is working on mathematical, statistical and verbal models of the labor force which integrate career and cross-sectional patterns of occupational achievement and earnings. The objective of these models is to provide a unified treatment of inter- and intragenerational mobility, compatible with status attainment, stochastic and log-linear treatments of socioeconomic achievement, lending themselves to labor force projections. RONALD J. D'AMICO is a candidate for the Ph.D. in the Department of Social Relations, Johns Hopkins University. He is currently engaged in research on labor market differences in the processes governing earnings attainment, and a cross-national analysis of the effects of dependency on patterns of urbanization.

■ FRED C. PAMPEL (Changes in U.S. Occupational Structure) is Assistant Professor of Sociology at the University of Iowa. He is presently studying the effects of occupational, industrial and economic change on the labor force and income status of the aged. KENNETH C. LAND is Professor of Sociol-

ogy and Director, Social Science Quantitative Laboratory at the University of Illinois, Urbana. In addition to ongoing work in the development of methods and models in mathematical sociology, he is currently engaged in the development of a large-scale dynamic sociological model of the United States for the post-World War II era. MARCUS FELSON is Assistant Professor of Sociology at the University of Illinois, Urbana. His current research is concerned with building indicator models of changes in crime rates, education, the military, and material life styles.

■ AAGE B. SØRENSEN (Inequality and the Process of Attainment) is Associate Professor of Sociology at the University of Wisconsin, Madison and, during the 1977/1978 academic year, Fellow, Center for Advanced Study in the Behavioral Sciences, Stanford University. His current research is on attainment processes and labor markets. His most recent book, with Annemette Sørensen, is *Mathematical Sociology: A Trend Report and a Bibliography*, Vol. XXIII No. 3 of *Current Sociology* (Mouton, 1977).

New Penguins in Sociology

EMILE DURKHEIM

His Life and Work: A Historical and Critical Study

by Steven Lukes

Praised in the *New Statesman* as "the best exposition of Durkheim in any language," this definitive biography is an in-depth analysis of the ideas and theories of the foremost French sociologist. Steven Lukes presents Durkheim's work in the context of his life and society and the intellectual and political climate of the times; he also offers a critical assessment of the lasting value of Durkheim's work for modern sociology.

IN NECESSITY AND SORROW

Life and Death in an Abortion Hospital

by Magda Denes

The most graphically honest book written on the subject of abortion. A well-written and powerful account of cold facts and complicated procedures as well as of human emotions. Dr. Denes relates not only her personal experience and conflict over her own abortion but those of patients and hospital staff inside a New York abortion hospital.

"...a stunning book...a sociological document of genuine import..."

—EDGAR A. LEVENSON, M.D.

CHARLES C THOMAS • PUBLISHER

INTRODUCTION TO LAW ENFORCEMENT AND CRIMINAL JUSTICE (26th Ptg.) by A. C. Germann, *California State Univ., Long Beach*; Frank D. Day, *Thomas M. Cooley Law School, Lansing, Michigan*; and Robert R. J. Gallati, *Chief of Police, Brockton, Massachusetts*. This volume delineates the role of law enforcement for the benefit of law enforcement personnel, citizens, and young men and women who are contemplating a career in criminal justice. The author clearly and comprehensively discusses the basics of criminal justice in relation to its philosophical background, history, constitutional limitations, agencies, processes, evaluations, and special problems. '77, 528 pp. (6 3/4 x 9 3/4), 3 il., \$13.75

STUDENT PROGRAMMED LEARNING GUIDE by Richard W. Snarr, *Eastern Kentucky Univ., Richmond*, and Larry N. Craft, *Univ. of Kentucky, Lexington*. Organized so that each chapter exactly parallels the chapters found in the Twenty-sixth Printing of **INTRODUCTION TO LAW ENFORCEMENT AND CRIMINAL JUSTICE**, this guide serves as a preview to key words, important concepts, individuals, places, and events. At the end of each chapter, one or more topics for discussion are included. '77, 120 pp. (6 3/4 x 9 3/4), \$2.00, paper

Books may be purchased separately or as unit. Combination price — \$15.75

CONTEMPORARY SOCIAL GERONTOLOGY: Significant Developments in the Field of Aging edited by Bill D. Bell, *Univ. of Nebraska, Omaha*. Foreword by Erdman Palmore. (61 Contributors) The entire spectrum of gerontological concerns is covered, including the demography and ecology of age; theories of aging; economics, housing and health; work, retirement and leisure; and attitudes toward age and aging. The contributors also discuss morale, adjustment and life satisfaction; the minority elderly; the institutionalized aged; and contemporary research strategies. '76, 480 pp. (6 3/4 x 9 3/4), 11 il., 99 tables, \$28.50

THE AMERICAN ALCOHOLIC: The Nature-Nurture Controversy in Alcoholic Research and Therapy (2nd Ptg.) by William Madsen, *Univ. of California, Santa Barbara*. The author of this book suggests that those on both sides of the nature-nurture argument are victims of their own tunnel vision. The available information on the biological, psychological and cultural aspects of alcoholism is examined in depth. The author concludes that a more complete approach, with a synthesis of various interpretations, is needed. This is a forthright text which calls into question many of the accepted ideas about alcoholism. '77, 272 pp., 4 il., \$11.50

CIVIL LITIGATION AND THE POLICE: A Method of Communication by Robert H. Sulnick, *Loyola Law School, Los Angeles, California*. The methods and research of this book are designed to show how law and social science, joined together, create the power and ability to functionally communicate with the policymakers in modern social institutions, specifically with the police. The book further shows that such a communication has the ability to cause the institution to change its policies. Contents include civil litigation, the police as a bureaucratic institution, police and authoritarianism, and the appellate courts and the power of the law. '76, 168 pp., \$10.75

POWER AND AUTHORITY IN LAW ENFORCEMENT edited by Terry R. Armstrong, *Park College-Crown Center, Kansas City, Missouri*, and Kenneth M. Cinnamon, *Gestalt and Social Competency Institute, Shawnee Mission, Kansas*. Foreword by Donald Kreps. (11 Contributors) Experts in police science, sociology, psychology and philosophy have contributed to this anthology on the uses and abuses of power. The first half of the text deals with perceptions and conceptualizations of power and authority. The latter half of the book focuses on the historical and philosophical development of administration and the psychology of police organization. '76, 208 pp., 1 table, \$13.50

New Viewpoints IN SOCIOLOGY

SEXUAL DEVIANCY IN SOCIAL CONTEXT

*Edited by Clifton D. Bryant, Virginia Polytechnic
Institute and State University*

Depending on the interpretive context, some sexual behavior may be classified as deviant when practiced in private, and tolerated as a necessary concession to the maintenance of social equilibrium when institutionalized as

group or commercial enterprise. This unique collection of 20 articles examines this dichotomy in various contexts to provide a deeper awareness of the inter-related nature of certain kinds of sexual activity and other configurations of socially sanctioned behavior.

Clothbound \$10.00 Paperbound \$6.95

CRIMINAL JUSTICE THROUGH SCIENCE FICTION

*Edited by Joseph D. Olander, Special Assistant to the Florida
Commissioner of Education, and Martin H. Greenberg, University
of Wisconsin at Green Bay*

Three aspects of the field of criminal justice—Culture, Community, and Crime; The Criminal Justice Process; and Criminal Justice Outcomes—are illustrated by 13 gripping science fiction stories. Each story is accompanied by a substantial introduction which critically appraises its specific concepts in terms of the study of criminal justice.

Clothbound \$12.50 Paperback \$6.95

ST. LOUIS

*Edited by Selwyn K. Troen, Ben Gurion University, and
Glen E. Holt, Washington University*

The first major contribution to St. Louis history since the turn of the century, this collection of documents and articles recreates the history of the city with particular reference to the processes by which it grew and to the problems entailed by its growth.

Clothbound \$12.50 Paperback \$6.95

YOUTH AND CHANGE IN AMERICAN POLITICS

By Louis M. Seagull, formerly, University of Pennsylvania

Views the political behavior of youth as following certain generational patterns, with youth as an agent for social, cultural, and political change—not as a consequence of recent extraordinary events, but as part of a basic cyclical societal evolution.

Clothbound \$10.00 Paperback \$5.95

FAMILY AND KIN IN URBAN COMMUNITIES, 1700-1930

Edited by Tamara K. Hareven, Clark University

Clothbound \$12.95 Paperback \$5.95

THE GRASS-ROOTS MIND IN AMERICA:

The American Sense of Absolutes

By Conal Furay, Webster College

Clothbound \$10.00 Paperback \$5.95

NEW VIEWPOINTS

*A Division of Franklin Watts, Inc.
730 Fifth Avenue, New York, N.Y. 10019*

What 9,120 people
have to say about
just about everything

It's all in one data file. Six national surveys conducted annually since 1972.

These surveys include replicated attitude questions on a wide range of topics, as well as a large selection of sociodemographic variables.

Each annual survey in the cumulative data set acts as a subfile. Since most of the questions were asked in more than one year, the user may also treat the file as a single large data set. The cumulative codebook provides full documentation.

The cumulative data set, including the annual General Social Surveys from 1972 through 1977, costs \$50. SPSS and OSIRIS system files can be obtained at an additional charge. Special files for the 1977 General Social Survey and other individual years are also available.

The General Social Survey is funded by the National Science Foundation and conducted by the National Opinion Research Center.

Questions about the General Social Survey may be directed to the project staff at the National Opinion Research Center, University of Chicago, 6030 S. Ellis, Chicago, Ill. 60637. The data sets are available through the Roper Public Opinion Research Center.

Data from The Roper Public Opinion Research Center

38 Mansfield St. Yale University

New Haven, Conn. 06520

New from Stanford

The City in Late Imperial China

Edited by G. William Skinner. Sixteen papers examine the traditional Chinese city from the perspectives of social scientists and institutional historians. Illustrated with over fifty maps and plates. Special endpaper maps show the cities of China in 1894 classified according to size, administrative level, and economic importance. \$35.00

Opportunity and Attainment in Australia

Leonard Broom & F. Lancaster Jones. Australia has long been perceived as one of the world's most egalitarian societies, one largely devoid of the special privileges, snobbery, and class distinctions of the Old World. Using evidence relating to education, jobs, and income, this study seeks to determine how much equality of opportunity and condition actually exists. \$12.50

Society and Homicide in Thirteenth-Century England

James Buchanan Given. Using quantitative and computer methods, the author analyzes the patterns of homicide in London, Bristol, and five English counties from 1202 to 1276, revealing that homicide was a frequent social phenomenon in medieval England, and, indeed, that violence was regarded as an acceptable, and often necessary, facet of life. \$12.50

Women in Russia

Edited by Dorothy Atkinson, Alexander Dallin & Gail Warshofsky Lapidus. Eighteen historians and social scientists discuss various aspects of Russian women's lives from the earliest times to the present, with an emphasis on their problems and opportunities in the Soviet Union today. \$18.75

The Rulers of German Africa, 1884-1914

L. H. Gann & Peter Duignan. The first book in a series dealing with the social structure of the European colonial services in Africa, this work examines Germany's military and administrative personnel in the colonies of German East Africa, South-West Africa, Cameroun, and Togo. \$17.50

Stanford University Press

HOUGHTON MIFFLIN UPDATE:

THE FAMILY, SOCIETY, AND THE INDIVIDUAL

Fourth Edition

William M. Kephart, University of Pennsylvania
1977/546 pages/Instructor's Manual
Contemporary, revised, expanded, and visually attractive, the new Kephart has optimum appeal for students. "The Changing Status of Women" and "Alternative Life Styles" are two of many new chapters.

UNDERSTANDING SEXUAL INTERACTION

Joann S. DeLora, San Diego State University; Carol A. B. Warren, University of Southern California; with contributions by Carol Rinkleib and Douglas Kirby
1977/642 pages/Instructor's Manual
Provides a comprehensive overview of the field of human sexuality. Covers latest research findings in both behavioral science and physiology.

SOCIAL PSYCHOLOGY

The Theory and Application of Symbolic Interactionism

Robert H. Lauer and Warren H. Handel
both of Southern Illinois University at Edwardsville
1977/487 pages/Instructor's Manual
Provides an introduction to social psychology from a symbolic interactionist perspective designed to give students materials for understanding human behavior and the stimulus to use those materials for analyses.

STATISTICAL REASONING IN SOCIOLOGY

Third Edition

John H. Mueller; Karl F. Schuessler, Indiana University; Herbert L. Costner, University of Washington
1977/544 pages/Solutions Manual
A careful revision of the widely used and highly respected introduction to applied social statistics. Emphasizes intuitive understanding of statistical reasoning rather than mathematical derivations.

MANNY

A Criminal-Addict's Story

Richard Pearson Rettig; Manuel Julio Torres; Gerald R. Garrett, University of Massachusetts, Boston
1977/264 pages/paper
An autobiographical account of a criminal-addict career covering one individual's experiences with juvenile gangs, drug addiction, prisons; includes chapters that relate theoretical literature and perspectives to the subject's life.

THE PURITAN WAY OF DEATH

A Study in Religion, Culture,
and Social Change

DAVID E. STANNARD

Philippe Ariès:

"Of the many books on death that have recently appeared, very few attempt to view the evolution of the phenomenon over a prolonged period of time; Mr. Stannard's work is one of those rare and happy few... a book that stimulates reflection."

Robert Nisbet:

"Its subject is superbly relevant to our time, and nothing more original in scholarship on the Puritans has been done since Perry Miller."

William A. Clebsch:

"Stannard gives us a look of revealing importance into the Puritans... A terse, urbane, learned, humane book."

The most famous book of our time, in paperback at last!

The history of *Roots* is staggering: 130,000,000 viewers—the *largest* audience in television history—saw the epic 12-hour drama. More than 1,400,000 purchased the hardcover book. And now Dell has published this monumental work in paperback—a book that will be an essential part of college courses for years to come.

An incredible seven-generation odyssey of Haley's family, *Roots* traces the birth of a West African child, Kunta Kinte, through the fight for freedom of pre-Civil War America and the ensuing struggle against prejudice. Dell 736 pages 17464-3 \$2.75

If you haven't already received a copy of the beautiful, full-color *Roots* poster, write us and we'll send you one.

Life Designs

Individuals, Marriages, and Families

John H. Gagnon, State University
of New York, Stony Brook / Cathy
S. Greenblat, Douglass College,
Rutgers University

March 1978, 640 pages, illustrated,
hardbound, approx. \$12.95, with
Instructor's Manual and Study Guide

Two leading sociologists explore marriage and family from a social learning perspective in a highly readable, fully illustrated presentation.

- Stresses continuous life-long socialization, role learning, gender development, relationship-changing factors, flexibility, and pluralism
- Uses a life-cycle approach to marriage, family, and sexuality, showing how behavior and attitudes change
- Translates theory into issues of personal values, behavior, and experience
- Features historical and cross-cultural perspectives, highlighting research findings, projected trends, and media portrayals of family life
- Offers non-prescriptive, non-sexist orientation
- Answers students' questions about marriage and family relations clearly and directly

Human Sexualities

John H. Gagnon, State
University of New York,
Stony Brook
February 1977, 432 pages,
illustrated, paperback, approx.
\$9.95, with Instructor's Manual
and Study Guide

Using the concept of social scripts, this basic text explores the social and psychological factors that shape the many variations of human sexual behavior at all stages of the life cycle.

Marriage and Alternatives Exploring Intimate Relationships

Roger W. Libby, State University
of New York, Albany
Robert N. Whitehurst, University
of Windsor
January 1977, 412 pages,
paperback, approx. \$6.95

Well-known authorities and writers from diverse fields present original articles (many published here for the first time) on the state of marriage and its alternatives in a changing world.

Criminal Justice in America

Process and Issues

Peter C. Kratcoski, Kent State
University

Donald B. Walker, University of
Michigan, Flint

February 1978, 500 pages, illustrated,
hardbound, approx. \$11.95, with Instruc-
tor's Manual

This comprehensive new text offers in-
depth coverage of the American
criminal justice process as well as of
critical issues facing the administration
of justice in our society today. A
chapter on cross-cultural perspectives
allows students to compare criminal
justice processes in the United States
with those in Sweden, Canada, and
France. In addition, chapters on juvenile
justice, legislation of criminal law, and
future trends in criminal justice make
this one of the most complete introduc-
tions to the field.

THE HITE REPORT

Sherie Hite • More than 3,000 women describe their sexual attitudes and experiences in "the biggest sex study since *Masters and Johnson*, even *The Kinsey Report*."—*National Observer*. "Real, significant, and poignant. . . . The whole rich variety of female sexuality is spread out in panorama."—Mary S. Calderone, M.D., President of SIECUS
Dell 13690-3 \$2.75

IT CHANGED MY LIFE

Betty Friedan • The woman who said it for millions in *The Feminine Mystique* herein describes the explosive events which followed the publication of that book. She refines and clarifies the recent history of the women's movement through essays, interviews, and personal revelations.
Dell 13936-8 \$2.25

THE FEMININE MYSTIQUE

Dell 12498-0 \$1.95

MAN'S WORLD, WOMAN'S PLACE: A Study in Social Mythology

Elizabeth Janeway • "You will not find anywhere a more closely reasoned, cogent, persuasive exposure of women's place. . . . This is a calm, controversial, frequently witty middle-ground exposition. A penetrating consideration of what is probably our most important problem."
—*Saturday Review Syndicate*
Delta 55163-3 \$3.65

MENSTRUATION & MENOPAUSE: Revised and Expanded

Paula Weideger • This ground-breaking book separates myth from fact in explaining everything that happens in a woman's body during each phase of the female cycle, from menstruation to menopause. In addition, it contains an update on the latest findings linking estrogen replacement therapy (ERT) to cancer. "Intriguing . . . I would recommend it to any reader."
—Maggie Scarf, *Ms* magazine
Delta 55845-X \$4.95

For a complete listing of Dell's paperbacks on Women's Studies, write for free brochure and college catalog.

THE MOTHER KNOT

Jane Lazarre • The author's painfully honest explorations of her own experiences with motherhood destroy the myth of the Good Mother and confront the feelings most mothers have been afraid to acknowledge—even to themselves. "Beautifully written . . . profoundly consoling and terrifying, her finds are universal."—Barbara Seaman, *Washington Post Book World*

Laurel 35798-5 \$1.95

MOTHERLOVE:

Stories by Women About Motherhood

Stephanie Spinner, editor • Seventeen writers look at woman-as-mother—her special relationship to herself, her children, and the world around her. Contributors include Penelope Gilliatt, Gail Godwin, Nadine Gordimer, Joanne Greenberg, Mary Lavin, Katherine Mansfield, Joyce Carol Oates, Tillia Olsen, Grace Paley, and Alice Walker. *February, 1978*

Laurel 35693-8 \$2.25

NOTES OF A FEMINIST THERAPIST

Elizabeth Friar Williams • Drawing on her experiences as a psychotherapist, Elizabeth Williams bridges the gap between feminist theory and the reality of individual women's lives. She discusses sex, love, work, money, motherhood, loneliness, depression, dependence, fidelity, and creativity, emphasizing that the ultimate goal is freedom from sex-role stereotyping.

Laurel 36427-2 \$1.50

SOLO: Women on Woman Alone

Linda Hamallan and Leo Hamallan, editors • Willa Cather, Doris Lessing, Jean Rhys, Joy Williams, and others present twenty-seven stories that confront the independence that has always been a natural, inevitable state for men. Enlightening, strengthening, mirroring aspects of all our lives, this collection speaks to the common experience more and more women are coming to perceive—and claim—as their own.

Laurel 38114-2 \$1.95

TELL ME A RIDDLE

Tillie Olsen • Four timeless pieces of fiction reveal Ms. Olsen as "a singular talent . . . a talent that prompts tears, offers the artist's compassion and forgiveness, but makes plain how fierce the various struggles must continue to be. Everything she has written has become almost immediately a classic."—Robert Coles

Laurel 38573-3 \$1.25

Delta 58573-2 \$2.45

WOMAN IN THE YEAR 2000

Maggie Tripp, editor • Twenty-six extraordinary writers and thinkers predict what will happen for women—and therefore men—by the 20th century. Their visions range from humorous, imaginative fantasies to serious, practical ideas, and contributors include Gloria Steinem, Alvin Toffler, Lois Gould, Caroline Bird, David Saperstein and Nora Sayre.

Laurel 39709-X \$2.25

WOMEN AND THEIR SEXUALITY IN THE NEW FILM

Joan Mellen • A professor of cinema analyzes the work of Bergman, Bertolucci, Bunuel, Rohmer, Visconti, Nichols, and others and their portrayal of women on the screen. "Brilliant . . . easily the best of the several recent books about the treatment of women in films."—*The Washington Post*

Laurel 39342-6 \$1.25

WOMEN & ANALYSIS: Dialogues on Psychoanalytic Views of Femininity

Jean Strouse, editor • This unusual book brings together the key writings about women by the major analytic figures from Freud to Erikson and then presents, in counterpoint, specially commissioned responses to these figures by writers such as Margaret Mead, Elizabeth Janeway, Karen Horney and Robert Coles. "An extraordinary book."—Nancy Milford, author of *Zelda*.

A text for today's society

SOCIOLOGY: THE HUMAN SCIENCE

Elbert Stewart, Bakersfield College

Thorough and up-to-date: SOCIOLOGY: THE HUMAN SCIENCE makes sure your students have the solid background they need in an introductory course. Yet it also uses frequent article inserts and detailed case histories to define difficult current topics such as race and ethnic studies, sex and age inequality, deviant behavior and political power.

Special chapters for special issues: Four innovative chapters—on Total Institutions; the Sociology of Work and Leisure; Stratification; Sex and Age; and The Interdependent World—focus on current issues and aspects of sociology that the average text just doesn't cover adequately.

Aids to understanding: This text is one of the few to incorporate its study guide into the text. Each chapter begins with learning objectives and concludes with a summary, a list of people and terms to know, 30 objective questions, and several discussion questions.

Why adopt SOCIOLOGY: THE HUMAN SCIENCE? Written for freshman-level reading and developed for rapid learning, SOCIOLOGY: THE HUMAN SCIENCE offers coverage of all the major sociological theories in a package that is stimulating, exciting and as current as today's headlines.

Exceptionally detailed Instructor's Manual. Test Bank featuring 1500 objective questions.

Introducing . . .
The Second Edition of this highly successful text

DONALD W. CALHOUN

SOCIAL SCIENCE IN AN AGE OF CHANGE

This highly readable introduction to the field provides a broad overview of basic social science principles and encourages the student to apply them as problem-solving tools in the development of a critical perspective on society. The fully updated Second Edition extends and strengthens the integrated approach, humanistic orientation, and innovative topical coverage that determined the success of the first edition. Featured in the Second Edition is a greatly expanded discussion of the roles of women and blacks in the American Economy. All material in the new edition—whether biophysical, sociological, psychological, cultural, ecological, anthropological, political, or economic—has been thoroughly updated. Tentative: 576 pages; \$12.95. Spring 1978. ISBN-0-06-041148-4. Study Guide: 160 pages, \$4.50/paper (tentative). ISBN 0-06-041149-X. Instructor's Manual.

Critical Issues in Organizations

Edited by STEWART CLEGG
and DAVID DUNKERLEY

*University of Bradford; and
Plymouth Polytechnic*

A distinctively European tradition of organization theory is now emerging, and at its centre is the European Group for Organization Studies (EGOS). Its main focus is upon an 'institutional' approach to the study of organizations, and the contributors to this volume all reflect this new approach. The critical issues discussed relate to sexism, power, capitalist development, organizational transactions and interactions, and the interpretation of State and Capital.

Paper \$9.75

The Sociology of Power

RODERICK MARTIN

Trinity College, Oxford

Roderick Martin argues that conventional definitions of 'political sociology' are no longer relevant, having been replaced by a revival of interest in wider problems, which need to be approached from new theoretical positions. In a reorientation of political sociology around the concept of power, he examines the sociology of power relations within industrial and political organizations of labour exploitation, and gives a critique of contemporary elitist theories.

International Library of Sociology \$12.95

Morals and Politics

The Ethics of Revolution

WILLIAM ASH

A presentation of the theory and practice of Marxist ethics, drawing on the relevant works of Marx, Engels, Lenin and Stalin, and an explanation of the moral aspects of Marx's dictum: 'The philosophers have only *interpreted* the world, in various ways; the point, however, is to change it.' Clearly written to 'demystify' the subject, the study challenges readers to test the author's enlightened, Marxist approach in terms of their existence in society.

Paper \$6.50

Puritan, Paranoid, Remissive

A Sociology of Modern Culture

JOHN CARROLL

La Trobe University, Melbourne

Western society has been transformed in the twentieth century; John Carroll questions assumptions of current sociological fashion and considers a deeper level of historical cause. He proposes three character types to indicate respectively the 'Puritan' past that is waning, the immediate 'paranoid' past that has exemplified the society's crisis of transition, and the 'remissive' future, whose ideology already permeates our present.

Give your students the innovative, probing new text with a single, consistent perspective on social problems . . .

Social Problems and the Quality of Life

by Robert H. Lauer
Southern Illinois University at Edwardsville

March 1978/ Approx. 600 pages/ Cloth/ About \$12.95*

Accompanied by:

Test Item File and Instructor's Resource Manual

(with over 1,000 items)
175 pages/ Paper/ Complimentary

Student Study Guide

150 pages/ Paper/ About \$4.95*

*Prices slightly higher in Canada

This innovative and probing new text presents your students with a thorough treatment of social problems in terms of their consequences for the quality of life. Lauer's quality of life perspective shows how social problems arise from the blocking and frustration of particular social expectations. These unfulfilled expectations and the consequent problems are discussed in detail—along with considerations for possible solutions.

Examine these important features:

Lauer gives your students a single, consistent perspective on the entire spectrum of social problems: the quality of life perspective provides a clarifying theme which allows students to see the wide and complex range of subjects from one unifying viewpoint. The quality of life perspective organizes the material for your students and confronts the major drawback inherent in any social problems course, i.e., the confusions produced by multiple and inconsistent perspectives.

The first three chapters prepare students to analyze the problems discussed in the remainder of the text by answering six important questions: What is a social problem?; How can we gain a sociological understanding of social problems?; What is Lauer's quality of life perspective?; How important is research methodology?; What kinds of thinking processes should we avoid in our attempt to understand problems?; What is the meaning and cause of a particular problem?

web

A special chapter, MYTHS AND FACTS: HOW DO WE KNOW?, alerts students to various fallacious ways of thinking about social problems. In all, ten different fallacies are discussed, and the ways in which they are applied to social problems are shown.

Lauer's quality of life perspective is applied in the consistent treatment of 13 contemporary American social problems. Each problem is examined with this thorough and consistent procedure: the necessary background information is gathered; each problem is analyzed as a contradiction that is incompatible with the desired quality of life; each problem is considered as a social phenomenon that has multiple levels of causation (both structural and social psychological); and the final part, "What Is To Be Done?," briefly offers some suggestions for resolving the problem.

A widening scope of social problems presents your students with many timely and relevant examples. Lauer moves from what are traditionally called problems of deviance to various problems of inequality and, finally, to global problems.

Special boxed inserts stress the importance of learning through personal involvement. Suggestions can be used either as individual or class projects, allowing instructors to build an active class around a set of projects.

Bring Lauer's innovative, probing new text to your social problems class. Order your examination copy today!

THE RISE OF PROFESSIONALISM

A Sociological Analysis

Magall Larson

"This is the most important book on professions to be published in years. Solidly grounded in the historical and sociological literature, it presents an authoritative analysis of the position of the professional-technician stratum in the political economy of the United States. It will serve as an essential scholarly resource for some time to come." —*Elliot Freidson*

327 pages, 12 tables, \$14.95

THE INEQUALITY OF PAY

E. H. Phelps Brown

Why does or should any one person earn eight times as much as another? The economist's answer relies mainly on supply and demand, but the sociologist finds more significance in the differentiation of the labor force by class, status, and power. This book examines both these ways of accounting for the inequality of pay, not at an abstract level but in the light of a wide and detailed study of the evidence.

Just published

The Capitalist State and the Politics of Class

Albert J. Szymanski

University of Oregon

Incorporating the best of traditional academic political sociology within the theoretical framework of Marxism, this unique text offers a thorough analysis of the state, politics, political processes, and political movements. The primary theme running throughout the text is that classes and struggles among classes are the essence of political sociology. Szymanski argues that: (1) the experiences of people as structured by their economic position in society ultimately determine their politics; (2) the class which runs and controls the corporate economy dominates the state in the United States and other advanced capitalist countries; (3) the state plays a central and growing role in stabilizing society, in facilitating the profit-making process, and in increasing economic productivity and the growth of corporate interests. Hard data is presented in support of the author's arguments, often in the form of easy-to-read tables. A truly interdisciplinary text, **THE CAPITALIST STATE AND THE POLITICS OF CLASS** will be a valuable addition to courses in both political science and sociology.

Problem Behavior and Psychosocial Development

A LONGITUDINAL STUDY OF YOUTH

By RICHARD JESSOR and SHIRLEY L. JESSOR

This book reports a social-psychological study of behavior and development in adolescents and youth. The authors are concerned with the interrelations of three major systems: personality, including values on independence and achievement, personal beliefs such as alienation and social criticism, and personal controls such as religiosity and tolerance of deviance; the perceived social environment, including parent and peer supports, controls, and models; and be-

havior, including drug use, sexual intercourse, drinking, activist protest, and aggression.

The book includes a detailed presentation of problem-behavior theory and of its implications for psychosocial development, a description of the longitudinal methodology, and a review of both cross-sectional and longitudinal findings.

Food, Stamps, and Income Maintenance

By MAURICE MacDONALD

A Volume in the INSTITUTE FOR RESEARCH ON POVERTY
POVERTY POLICY ANALYSIS Series

SECTION HEADINGS: An Analytical History of the Food Stamp Program. How the Food Stamp Program Works. Food Stamps versus Cash Transfers. Nutritional Effects of Food Stamps and Experimental Cash Transfers. Food Stamps

and the Income-Maintenance System. Participation in the Food Stamp Program. Alternatives for Food Stamp Reform.

1977, about 175 pp., in preparation
ISBN: 0-12-464050-8

The New Jersey Income-Maintenance Experiment

VOLUME 2:

LABOR-SUPPLY RESPONSES

Edited by HAROLD W. WATTS and ALBERT REES

A Volume in the INSTITUTE FOR RESEARCH ON POVERTY MONOGRAPH Series

The New Jersey Income-Maintenance Experiment is a new three-volume series on the first experiment to test the effects of a negative income tax.

Volume 2: Labor-Supply Responses analyzes data from the experiment relevant to the central question the experiment was instituted to answer: To what extent a negative income tax would tend to diminish the work effort of program beneficiaries. The volume contains regres-

sion analyses and other statistical treatments of work behavior responses of various family members to the payments. Although it is more technical than the first volume, it may be considered the most important volume of the series for its treatment of work behavior, the central focus of the experiment.

1977, 440 pp., \$28.50/£20.25

\$13.95

EXISTENTIAL SOCIOLOGY

JACK D. DOUGLAS and
JOHN M. JOHNSON, Editors

In the first systematic and critical attempt to solve the basic weaknesses of phenomenology and ethnomethodology, ten original essays emphasize the relative independence and dominance of human feelings over the evaluative and cognitive aspects of social action, and the implications this holds for a total, empirical social science. Hardcover \$25.00 Paper \$7.95

PORTRAITS OF WHITE RACISM

DAVID T. WELLMAN

Five individuals—a longshoreman, a Head Start worker, a middle-class businessman, a well-to-do financial director, and a southern girl in Haight-Ashbury—tell how their lives intertwined with the lives of blacks in narratives that are used to demonstrate how people come to grips with racial conflict. Dr. Wellman concludes that people do not have to be prejudiced to think and act in ways that maintain a racial status quo. Hardcover \$16.95 Paper \$5.95

FAMILY LIFE AND ILLICIT LOVE IN EARLIER GENERATIONS

Essays in Historical Sociology

PETER LASLETT

Topics covered include the function of servants in traditional English society, the high turnover of population in pre-industrial England and Europe, the age of menarche and its variation over time, and the familial structure of Southern slave populations. Hardcover \$24.50 Paper \$8.95

NEW FOR

THIS LAND OF PROMISES

The Rise and Fall of Social Problems in America

Edited by Armand L. Mauss, Washington State University; and Julie Camille Wolfe, University of Montana

A stimulating collection of twenty-five articles structured around a central theoretical perspective: that social movements are closely related to, and in some sense reinforce, social problems. The articles

range over problems of inequality, crime and sex, alcohol and drugs, political protest and the environment. The author-editors have prepared an extensive general introduction outlining their theoretical stance, introductions for each section and an epilogue.

452 pages/1977/paperbound, \$5.95

Second Edition

CORRECTIONAL INSTITUTIONS

Edited by Robert M. Carter, Daniel Glaser, University of Southern California; and Leslie T. Wilkins, State University of New York, Albany

This well balanced introduction to corrections comprises thirty-eight articles — of which twenty-seven are new to this edition — that cover the history and current status of prisons and prison systems, with particular emphasis on the problems of the

inmate. While retaining the structure of the first edition, this new edition stresses new approaches to correction, including community programs and innovative programs within prisons.

571 pages/1977/paperbound, \$7.95

Lippincott

ESSENTIAL STATISTICS FOR SOCIAL RESEARCH

Michael A. Malec, *Boston College*

Designed for students with limited mathematical background, this concise text provides enough of the basic matter of statistics to enable them to read sociological literature with some appreciation of the

function and significance of statistics. The content of this helpful book is limited to those statistics regularly used by sociologists.

235 pages/1977/paperbound, \$7.95

Fifth Edition

MARRIAGE AND FAMILY DEVELOPMENT

Evelyn Millis Duvall, *Family Life Consultant*

Completely rewritten and updated, this new edition includes data and findings from the latest research in the areas of marriage and family. New material includes such topics as: alternative forms of marriage; marriage contracts; sex differences and gender roles; marital options;

changing sexual attitudes and behavior; death of family members; dissolution of marriage; social change; and racial and ethnic differences. The life-cycle approach has been retained; keyed references, tables and charts amplify the text.

559 pages/1977/clothbound, \$12.95

OFFICIAL DEVIANCE

Readings in Malfesance, Misfeasance, and Other Forms of Corruption

*Edited by Jack D. Douglas, University of California, San Diego;
and John M. Johnson, Arizona State University*

Comprehensive and up-to-date, the articles in this collection range over sociological analyses, government reports, historical and journalistic accounts, and comments by participants. Three initial articles define political corruption and show how criteria vary for defining corrupt

behavior in different times and societies. Coverage includes Watergate, CIA and FBI scandals, the NYC fiscal crisis, Kent State, Attica, and Washington lobbying. Each section has a brief introduction, and the last section offers proposed solutions to problems of official deviance.

396 pages/1977/paperbound, \$5.95

FAMILY STRUCTURE AND INTERACTION

A Comparative Analysis

Gary R. Lee, *Washington State University*

In this book the author demonstrates how comparative research has contributed to theory development in the sociology of the family. The focus throughout is on knowledge about family structure and behavior which has been generated, refined or ex-

tended by comparative research. Organization is topical, rather than systemic, with the objective of explanation rather than description. Controversial topics include premarital relations, sex roles, and the relationship of roles to conjugal power.

343 pages/1977/clothbound, \$9.95

NEW FROM COLUMBIA

ESSAYS IN SOCIAL THEORY

Steven Lukes

From the author of *Emile Durkheim: His Life and Work* comes this solid collection of essays on such recurrent problems in sociology as theory-making and evidence, power and structure, and the alleged relativity of standards of rationality and validity. Two essays on Rawls's *Theory of Justice* and Nozick's *Anarchy, State, and Utopia* lend the volume special interest. \$13.00

POLITICAL SOCIETY A MACROSOCIOLOGY OF POLITICS

Edward W. Lehman

Believing that large-scale groups, such as political parties, business corporations, and labor unions, are crucial in shaping our political life, Lehman cogently analyzes and defends the traditional concerns of macrosociology as expressed in the political affairs of complex modern societies. \$15.00

ESTRANGEMENT, ALIENATION, AND EXPLOITATION A SOCIOLOGICAL APPROACH TO HISTORICAL MATERIALISM

John Torrance

By developing the fundamental concepts of estrangement, alienation, and exploitation, this study aims to construct a formal sociological scheme that can plausibly be seen as implicit in Marx's work and relevant to subsequent sociological theory. Torrance makes plain the immense stimulus and resource Marx represents for modern sociology. \$22.50

CHILD MALTREATMENT IN THE UNITED STATES A CHALLENGE TO SOCIAL INSTITUTIONS

Saad Z. Nagi

The timely, if tragic, subject of child abuse and neglect in the United States is dealt with in the most current and comprehensive study of child maltreatment yet undertaken. This significant work will interest specialists in child welfare, sociology, medicine, government, and law. \$8.00

Presenting
a landmark text
in criminology...

CRIMINOLOGY
Gresham M. Sykes

University of Virginia

In this extraordinary new introduction to criminology, Gresham Sykes has written a comprehensive textbook of exceptional imagination, objectivity, and intellectual richness that speaks clearly and vigorously to students. Instructors and students alike will be exhilarated by this broad, balanced presentation of the nature and causes of crime, the content of the criminal law, the workings of the criminal justice system from arrest to trial, and society's various and changing reactions to crime and the criminal. The book includes superb discussions of such controversial issues as the politicization of prisoners, the relation of crime to the social system, political and white-collar crime, and contemporary views of the idea of rehabilitation. An outstanding chapter on the world of the prison describes the inmate subculture, and Professor Sykes' analysis of probation and parole is direct and up-to-date. Each of the book's five parts opens with an introduction, and each chapter concludes with a summary and an annotated list of further readings. Photographs and boxed inserts reinforce the text presentation.

Instructor's Manual

...and the classic text
in social problems

**CONTEMPORARY SOCIAL
PROBLEMS**

Fourth Edition

Edited by **Robert K. Merton** and
Robert Nisbet

both of Columbia University

Among the most respected, successful, and influential textbooks in sociology, *Contemporary Social Problems* brings together 17 original essays dealing with major social problems, all written by leading authorities in their fields. All selections are fully up-to-date and are shorter, livelier, and less technical than in previous editions. Instructors agree that the Fourth Edition of this traditionally sound, authoritative text is the finest and most useful of all —
"It is without an equal in the field."

— LEO SROLE, Columbia University

"... the best edition published. It not only deals objectively with the major social problems of society, but it clearly emphasizes the theories and perspectives of the discipline."

— ERNEST M. SHULL, Saint Francis College
... an excellent survey of the subject matter, especially for the beginning student."
